

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

- + *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
- + *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
- + *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
- + *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter <http://books.google.com> durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

AN HISTORIC RÉSUMÉ OF THE PROGRESS OF SURGICAL SCIENCE.

ABSTRACT OF AN ADDRESS DELIVERED AT THE INAUGURAL MEETING OF THE JUNIOR SURGICAL SOCIETY OF IRELAND.

By J. FITZSIMONS, Esq.,
Auditor of the Society.

ALL who have been great in our profession have exercised the faculty of observation to the utmost, and have been diligent in taking notes; for instance, Laennec, when he was Corvisart's pupil at hospital, took notes of 400 cases. He and those who pursued the same course had their reward in the immense progress of the art to which they devoted their energies; that progress has been ever steadily advancing, while many other professions have remained stationary, or have retrograded. The builder and engineer of modern times have not produced works which can compare, in grandeur and durability, with those of ancient Egypt, Greece, or Rome. The modern sculptor despairs of rivalling the shattered remains of the chisels of Phidias and Praxiteles. What orator has surpassed Demosthenes in force, or Cicero in elegance? But even if we were to revive the once famous controversy about the merits of the ancients and moderns, the most blinded admirer of the former could not deny the advance that all branches of medicine have made, and though it is still far from taking a place among the exact sciences, we may hope that it will approach very near to them.

In order to understand the progress that has been made, let us look back to the origin of our art. Leclue endeavours to show that the first man was also the first physician; but I am afraid that the proofs of this high antiquity are not very satisfactory. The Egyptians seem to have cultivated medicine from a very remote period; the knowledge of it was confided to their priests and like the mysteries of their religion, carefully kept from all but the initiated. In the early days of Grecian history we find men-

tion made of the healing art, but no trace of correct observation nor true principles; and the whole subject is so overburthened with superstitious practices that progress was impossible. In Hippocrates, of Cos, we find the dawn of better things. As we study his ideas we can with difficulty realise that 2,000 years have elapsed since they were first entertained; nor can we fail to admire the industry of this pioneer of medical science who has left us treatises on ancient medicines, surgery, prognostics, epidemics, fractures, injuries to the head. In his work on surgery he describes minutely surgical appliances, and in his treatise on epidemics we find accurate description made of *forty-two* cases of fever, and days of crisis pointed out. There was, as we might expect, much error mixed with these germs of truth; he considered, for example, that the body was composed of what were then called the four elements—"fire, air, earth, and water;" and he speaks of there being four humours of the body—blood, phlegm, yellow bile, and black bile. He considered health depended on these humours remaining in due proportion, if the balance were disturbed the result was disease; the nature of the disease, he goes on to say, varied as one or other was in excess. This was the origin of his humorous pathology, which held its ground for centuries; we can trace it even in the derivation of the word calomel—*kalos* and *melus*, as it was supposed to be an effectual remedy for a preponderance of the black bile—nay, do not unconsciously to this day pay homage to the theory of the old Greek when we speak of being in a good or bad humour. Hippocrates bestowed much attention on the important subject of hygiene, and his views on it will be found in his work on air, water, and places. The followers of Hippocrates formed themselves into a school, which was called the "Dogmatic;" they deduced their mode of cure from theoretical dogmas; while in opposition to them arose another, the "Empiric" school, who professed to derive theirs from experience only. There was yet another school, called the "Methodic," which was founded by Asclepiades, of Bithynia, who seems to have been a quack, who spoke with contempt of all views received at his time, gave a list of new medicines, and boasted of wonderful cures effected by them; some of his views, however, were

sounder; he first divided disease into "acute" and "chronic;" he was a great advocate for friction, cold bathing, and is said to have invented the shower-bath.

The next great name we meet with is Galen, five centuries after Hippocrates; but much had been done meanwhile. A great school of medicine had been established at Alexandria, and great advance had been made in medical science, but chiefly in anatomy. We find Herophilus and Eristratus dissecting the human body, and are even accused in their zeal of having dissected criminals alive. Eristratus described minutely the structure of the heart. Rufus, of Ephesus, applied himself particularly to the study of anatomy; he dissected apes—perhaps in anticipation of the Darwinian theory that in the ape he found the prototype of man; he traced nerves to their origin, and divided them into those of sensation and voluntary motion; he pointed out the decussation of the optic nerve, and he speaks of the capsule of the lens; the heart he believed to be the seat of life and cause of pulsation, and he showed the difference in size and capacity between the right and left ventricle. Marinus also described the absorbent system and mesenteric glands; he distributed nerves into eight pairs, and is said also to have discovered the "par vagum." Neither had materia medica been neglected: Dioscorides wrote a work which was held as an authority for 1,500 years; he describes such valuable drugs as assafetida, opium, squills, also the efficacy of elm bark in cutaneous diseases. Surgery, also, had made progress; Ammonus invented an instrument for crushing stone. Nicetus, in the time of Trajan, gives a description of the operation for cataract, and recommends it to be done where small. Leonides, of Alexandria, made several observations on glandular swellings, hernia, hydrocele, and his operation for fistula differs but little from that recommended by Pott. To Menacretes we are indebted for the discovery of diachylon plaster. As a proof of what observers they were in those days, we find one Cassius, in his book on medical problems, remarking that ulcers do not heal till they are on a level with surrounding tissue; that parts round the seat of injury remain unaffected while remote parts suffer, as the glands in the inguinal region after injury to the foot; that an injury to one side of the head is followed by paralysis of the other side of the body; and he explains this by pointing out that the nerves decussate at the base of the brain.

Another genius now arose—Galen, who flourished 131 years after Christ; he entered on his medical studies when only 17 years old, and died at the age of 70. He was a follower of Hippocrates. He is said to have written more than 150 essays on different subjects; his "Ars Medica" was the text-book at the school of Salerno centuries after. He considered increase of temperature to be the essence of fever, thus agreeing with what Virchow says in the present century. His description of the bones and muscular system is most accurate; his views, however, on the circulation were not so correct, as he believed the liver to be the origin of the veins, and the arteries to contain air mixed with a spirit. No notice had been taken hitherto of the pulse; he made it the great study of his life, wrote fifteen treatises on it, and insists on its being taken into consideration with other symptoms. He describes also the corpus calcosum, fornix, &c. Time will not allow me to dwell on all this great man achieved: his works abound with reasoning and hypothesis; he was not so close an observer as Hippocrates, who recorded only facts, observed either by himself or others. After the death of Galen science declined. Medicine, like many other departments of knowledge, suffered an irreparable loss by the burning of the great library of Alexandria by the invasion of the Saracens. The Arabs themselves, however, soon afterwards turned their attention to medicine, and they were the only people who did so at this period. In anatomy they could not make much progress, as dissection of the human body was strictly forbidden by their religion; but careful observations were made. Phases gave an accurate description of small-pox and measles, and distinguished between the superior and inferior

laryngeal nerves. Unfortunately, magic, astrology, and alchemy formed also, at this period, part of the physician's studies. Alchemy had at least one good result, as it prepared the way for chemical discoveries which were afterwards of practical utility. Geher, in the 8th century, is said to have been acquainted with preparations of mercury, such as corrosive sublimate and red precipitate. They cultivated pharmacy assiduously, and the first pharmacopoeia appeared early in the 9th century. The Arabs established what were called dispensaries, and sold medicines at a fixed price. Avisenna is the most distinguished name amongst them; his greatest work was his "Canon of Medicine," which was used down to the 15th century. In the 12th century the Benedictine monks established the school at Salerno, at which every claimant, for the honour of a diploma was made to swear that he would not take a fee from the poor, nor have any share in the gains of the apothecary. This school became very famous, and must have been well supplied with a great number of interesting cases, as Salerno was frequently a halting place for the crusaders; but, unfortunately, its professors contented themselves with translating the works of the Arab physicians, and neglected, to a great extent, those of the Greeks, which contained more correct ideas on anatomy and physiology. It is a remarkable fact that ladies were admitted as students, and not a few distinguished themselves, of whom Constantia Calenda was the most celebrated. This circumstance, perhaps, accounts for the ceremonial of conferring the degrees, which consisted in the learned doctor placing a book in the hand of the candidate, a ring on the finger, a wreath of laurel on the head, and imprinting a kiss on the cheek.

It required some courage, however, to be a surgeon in those days, for, if one were unsuccessful in operating he was handed over to the friends of the patient, to be dealt with as they thought fit. Several medical schools were now founded in Europe; the most important were those at Paris, Montpellier, Bologna, and Padua. The Italian schools were very successful, for we find that Mundinus took the bold step of publicly dissecting two bodies. European physicians had also to contend with diseases suddenly introduced from the East, to treat which they were ill prepared; of these the plague and leprosy were the most fatal. We first hear of the plague in Tche, in China, where alone 5,000,000 perished; it then swept westwards, reaching England in August, 1349. For two years it desolated Europe, carrying off 25,000,000 of its inhabitants. Unfortunately, physicians have not left us much information about it, or what their treatment was.

After the battle of Cressy surgeons had to turn their attention to gun-shot wounds. Their plan of pouring boiling oil or pitch into the wound on the supposition that they were poisonous, must have caused intolerable anguish to the patient, till Ambrose Paré, who has been termed the Father of French Surgery, discontinued the practice. His supply of oil having once run short, he had, with much misgiving, to dress the wounds without it; but, with great surprise and satisfaction, found next day that they looked far healthier than those that had been dressed in the old manner. Since then wounds have healed in a rational manner. He also introduced the use of ligatures, and confesses in one of his works that he got the idea from Galen. When he instituted this practice in his own country the Faculty of Medicine in Paris laughed at him, and said it was folly to hang life upon a thread. As early as 1483 Fracastorius accurately describes typhus fever, and says that all those who were bled for this disease perished.

Paracelsus, in 1493, whose genius is beyond dispute, but spoiled by conceit, with as much presumption as bad taste, commenced a course of lectures on medicine by publicly burning the works of Galen and Avicenna, and saying that his shoe-latchets possessed more knowledge than the ancients, and his beard more experience than all the academies in the world. He held the extraordinary doctrine that a demon resided in the stomach, who pre-

sided over what was nutritious, and the reverse. All disease was caused by this governor, he says. Paracelsus, however, did some good to advance medicine; he was the earliest teacher of chemistry. He was the first to lecture in German, and not in Latin; and we are indebted to him for introducing mercury into practice, and for discontinuing the use of complex prescriptions. The sixteenth century is remarkable for the great advance made in anatomy. We are all familiar with the names of Vesalius, Falcius, Etrium, and Falopius. The valves in the veins, and how the blood circulated, were the subjects that engaged the attention of those great men, and occasioned warm disputes among them. These controversies, however, led to the establishment of several facts which smoothed the way to the final discovery that has rendered the name of Harvey immortal. Servetus, as early as 1534, described the pulmonary circulation.

Paré, to whom I alluded before in reference to gun-shot wounds, made accurate observations on the reduction of hernia. He also distinguished between fracture of the neck of the thigh-bone and dislocation, with which it had hitherto been confounded. He is said to have written twenty-six treatises on every subject of surgery.

In the latter half of the sixteenth century Lord Bacon caused a great revolution in the mode of investigating all branches of science, and his comprehensive mind saw how much medicine also would gain by the application of the "inductive method." He therefore recommended physicians to observe more for themselves, to give their attention more to pathology, and not to trust implicitly to the opinion of the ancients—which last suggestion was soon followed by Van Helmont, who endeavoured to expose the errors of the humorous pathology, but had the bad taste to ridicule its originators. Unlike the noble-minded Harvey, who, though he saw still more clearly the errors of Galen, respected what was great in him, and always spoke of him as the "Divine Galen," some of Van Helmont's views would be liable to the same fate now, for he believed in the existence of a "vital spirit" which controlled the actions of the body, and he accounted for digestion by saying that this spirit generated the acid in the stomach which dissolves food.

But the era of correct ideas on physiology was now at hand. In 1578 the great William Harvey was born. To understand all that the science of medicine owes to him we have only to consider that up to this period the heart was supposed to be a mere reservoir for the blood, the arteries to contain only air mixed with a spirit, and the origin of veins to be seated in the liver. I need not dwell on the great event of his discovery; it is a subject we are all familiar with, and we can with difficulty believe the grave opposition it received from some of his contemporaries, nor the mockery that styled him the "circulator;" but the unusual good fortune was reserved for him of living to see his theory universally accepted, and himself an object of veneration. The circulation of the blood was not the only subject on which he thought correctly, which he studied diligently. He suspected another truth when he says the heat of the body increased by respiration, and not as was commonly supposed, cooled. His great work on "Generation" contained the observations of a long and studious life, which was prolonged to the age of 80 years.

It has often been remarked how history repeats itself; and now, in the seventeenth century, we find the students of medicine again divided into three schools—the "Chemical," the "Mechanical," and the "Spiritualistic." The most prominent figure in the chemical school was Francis de la Boi Sylvius, who has also been said to have been the first clinical teacher. Sylvius, attracted by the notion of alkalis and acids, and their mutual action, framed a system on it. Observing that the lymph contains an acid, and bile an alkaline salt, and that these two acid substances, when brought together, neutralise each other, he attributed all disease to an excess of either principle, and prescribed the other as its cure. This Jaho-chemical school, like most schools, pushed its favourite doctrines

too far; but this tendency was corrected by the celebrated Robert Boyle, whose turn of mind inclined him to suspect generalities; he pointed out some grave errors they committed, and recommended physicians to first ascertain correctly what the disease was, and to give a medicine which they knew by experience to be effectual. All else he believed to be vain conjecture.

The mechanical school arose in Italy, under the leadership of Borelli, and though they fell into some errors through the same tendency as the chemists, particularly when they theorised on the treatment of disease, still, science owes them much, for as long as they confined their researches to the structure of the frame they proceeded on true scientific principles, and established facts which remain good to this day. Sanctorius discovered the insensible perspiration, and also the thermometer. Borelli gave an accurate description of the actions of muscles, and compared the heart to a pump. But he and Bellini made a great mistake when they tried to account for fever on the laws of hydraulics—namely, that the phenomena of fever depended only on the rapidity of the circulation, and in no way on the nature of the blood itself,—so putting cause for effect.

The spiritualistic school was founded by Stahl, who believed that the soul presided over the functions of the body. The ardent partisans of these medical sects, as was only to be expected, degenerated into quacks, a class of enemies to whose invasions the realm of medicine is peculiarly liable, partly from the nature of the subject, but still more from the ready reception they receive from a credulous public. But they met with an able antagonist in Thomas Sydenham, a thoroughly practical man, accurate in observation, and one whose description of disease has never been surpassed. He has left us works on fevers, gout, hysteria, colica pictonum, and rheumatism. He paid particular attention to phthisis, and considered horse exercise almost a specific in this disease, as well as Peruvian bark in ague. This valuable drug was introduced at this period. As a proof of its efficacy I may mention the fact that in seven years before its coming into use in this kingdom 10,600 people died of ague; and after it had been for some time in use the fatal cases were reduced to 31 in the same period. It has been well said of Sydenham that he was daring in practice, respectful of the past, but acting strongly in the present, and with rare independence. On his tomb was inscribed that he was one of the nobles of medicine, with more truth than is often found on epitaphs.

The great Haller now appears, who did for physiology what Sydenham did for medicine. He placed it on a sound basis, proved that muscles possessed an inherent power of themselves, which he termed irritability, and by which they contracted independently of nervous influence. He also proved that irritation of the phrenic nerve produced contraction of the diaphragm. He made many other contributions to science; but I cannot here dwell on them, nor on his wonderful attainments in other branches of learning.

Descartes' theory of nervous force was at this time generally received; and although we do not now refer this force to the presence of animal spirits, still, his fundamental ideas were correct, as they were ably set forth by Prof. Huxley at the recent meeting of the British Association at Belfast.

The Scottish School of Medicine became about this period the foremost in Europe, and students were attracted there in great numbers by the teaching of the justly celebrated Cullen, who was equally with Sydenham a practical man, a great physiologist, and whose classification of disease was excellent.

Cullen and Wm. Hunter were great friends. The latter was now in London, where his splendid lecturing, particularly in "Obstetric Medicine," presented this branch almost as a new science. His fame attracted his brother John to London, one of the most patient and industrious investigators that the world has ever seen, and who well deserves what has been said of him, "that he found sur-

gery a mechanical art, and he left it a science." I need not say that he made himself a great anatomist. In surgery he has never been excelled. His most brilliant operation was the tying of the femoral artery for popliteal aneurism, 1785. He was the first who treated aneurism on truly scientific principles—namely, tying the artery at a distance from the seat of disease. If surgery owed him nothing but the formation of his splendid museum, it would be a great debt, for not only the 10,000 preparations it contains are perfect in their way, but the impetus it gave to the formation of similar collections has been of incalculable use. Also by it we can estimate the industry of the man, and the deep interest he took in all relating to pathology. Other evidences of the advance made in surgery, both as an art and as a science, we can see by looking to what Sir A. Cooper did. He first tied the carotid for aneurism, on the principle laid down by Hunter. In 1817 he had the courage to tie the abdominal aorta, having previously experimented on some of the lower animals. The treatment of aneurism by ligature has now been almost entirely superseded by pressure, and to the Dublin School is chiefly due the merit of having introduced this mode, which has innumerable advantages, as may be studied in the exhaustive treatise of the distinguished gentleman who now occupies the chair. Sir A. Cooper has also left us great works on hernia, fractures, dislocations, &c.

A little before this period an experiment in medicine was made which was followed by surprising and important results. I allude to vaccination, which has been the means of preventing the most terrible pestilence of modern times, that from the seventh century up to this period had baffled the most skillful. It has been calculated that there perished of this disease alone in Europe 210,000 annually, and in England 40,000. It has been said of Jenner, by those who take pleasure in detracting from the greatness of great men, that he would not have made this discovery had he not lived in a pastoral district. But many medical men had been in the same circumstances before, without having been led to it. Rather let us give all credit to Jenner, and learn from him not to neglect any source of information, however humble. We are all aware that his first ideas on this subject were drawn from the observations of the peasants among whom he lived. Nor can I leave the subject without alluding to the intelligence and courage of Lady Wortley Montague, who first introduced into England the custom of inoculating for the small-pox, and thus prepared the way for vaccination.

Few medical subjects are of such interest and importance as that of fever. During the last thirty years, in England and Wales alone, the different varieties have destroyed 530,000, and the actual number of persons attacked, to judge from this mortality, must have been between five and six millions. Various have been the theories as to the nature and cause of fever. We have seen how Hippocrates believed it to be due to an excess of one or other of four humours, and again, the mechanical school subjecting it to the laws of hydraulics. In the beginning of the present century, however, its pathology began to be attentively studied in France. Great attention was paid to the intestinal lesions found in typhoid fever, but it was erroneously believed that the local disease caused the fever, and was always in proportion to severity of attack. Broussais some few years afterwards considered enteric fever as only the type of a series which he classed by the name of *gastro-entérite*, believing that an inflammatory state of intestines was the cause of pyrexia. He maintained, also, that variola, measles, scarlet fever, were all due to this *gastro-entérite*; hence, acting on the supposition that inflammation was the cause, he used depletive measures largely. It was reserved for Bretonneau, in 1820, to point out that the lesions in enteric fever were secondary effects of a poison introduced into the system, and Robert Graves at this period, also in Ireland, investigated thoroughly the nature of fever. He concurred with the views of Bretonneau, and they exposed the errors into which

Broussais had fallen. Speaking of the two physicians, Trousseau says they passed their youth in contending against the abstinence from food in fevers, and to them is chiefly due emancipation from the yoke of prejudice imposed on practitioners by the school of Broussais. Graves, he goes on to say, is a man whom I regard as the most eminent clinical teacher of our age, whom I delight to quote, whom I constantly consult, and whose work ought to be your *vade mecum*. Graves pointed out clearly how close a resemblance the symptoms caused by long-continued want of food bear to the worst forms of typhus. He said to his pupils, if at a loss for an epitaph for my tomb, say "that he fed fevers." The giving of stimulants in fevers—to know when to do so, and not—is of the utmost importance, and Dr. Stokes, as early as 1839, pointed out that the grand criteria for guiding are the states of radial pulse and heart. I am sure I do not say too much when I maintain that to the system of clinical teaching founded by Graves and his colleague Dr. Stokes is mainly due the fame that attends Dublin as a school for practical medicine.

The advance in the study of pathology within the last thirty years is truly wonderful. In this the microscope plays a most important part. The nature and cause of phthisis is now being rapidly cleared up. Though the belief is still wide spread that phthisis depends only on diathesis—mainly this the doctrine of Laennec—his assertions that "catching cold," and other irritations, do not produce tuberculosis, we do not now hold to. There can be no doubt that the majority of the cases are not the result of neoplasm, but of inflammation, and that the said catching cold more than anything else predisposes to this fatal disease. Dr. Lyon Playfair says, speaking of this malady, that it is greatly to be mitigated by drying and ventilating the soil, as well as by sanitary dwellings. In Salisbury, after the sewerage had been made effective, deaths fell 49 per cent; in Ely, 47; and in Rugby 43. In the last generation the average duration of the disease was ten years; now, according to Dr. Williams, it is eight years.

Since the discovery of Sir C. Bell—on the function of the spinal cord—a discovery which is said to equal that of Harvey—the physiological anatomy of the nervous system has been thoroughly investigated, and we can now discriminate between many diseases which a short time ago were confounded. The geography of the brain has now been mapped out, and the brilliant results of the experiments lately carried on by Fritsch, Hitzig, and Ferrier show that the ideas involved in what is called phrenology have, after all, a scientific basis. The attention paid now to sanitary science is a true sign that we live in a progressive age. The mortality in London a century ago was more than 35 per 1,000; at the present time, notwithstanding the immense increase in population, it is only 22 per 1,000. The mortality in Calcutta and Bombay, which was formerly something appalling, is now the same as some of the large cities in England.

CHOLERA: ITS ÆTIOLOGY, CONTAGIOUSNESS, AND TREATMENT.

By WM. BOYD MUSHET, M.B. Lond., M.R.C.P.,
Late Physician to the North London Hospital for Consumption, formerly
Resident Physician at St. Marylebone Infirmary.

ÆTIOLOGY.

(Continued from page 565.)

PROFESSOR MACLEAN is evidently a contagionist, and Inspector-General John Murray, of the Indian Service, thinks it to some extent contagious or communicable, but that there is not very great danger in attending on the sick in Great Britain, where decomposition is comparatively less rapid than in India. It may be remarked that Dr. Murray states he has suffered from three attacks of cholera, and this testimony is opposed to its being an

acute specific disease, which usually occurs but once to the individual.

Dr. Snow, who threw so much light on the ætiology of the epidemic, also thought that it was contagious or communicable from person to person.

Dr. Gavin Milroy thinks contagion plays a very small and subordinate part in the diffusion of cholera, and that it does not admit of doubt that it may arise *de novo*, and make its appearance at intervals in Hindostan quite independently of any suspicion of antecedent importation. Dr. Bastian holds similar opinions.

Dr. Cuninghame, Sanitary Commissioner with the Government in India, in consequence of facts especially collected, arrives at the conclusion that the evidence is entirely against the contagiousness of cholera. He denies that it is a specific poison capable of multiplication in the bodies of those affected, or that it can be transmitted through the medium of water, or that human locomotion has anything to do with its propagation from place to place. Dr. Cuninghame deems air to be the only agent worthy of serious notice in the propagation of the disease, and insists emphatically on a pure water supply, and on removal from infected districts—*i.e.*, withdrawal from the conditions with which the pestilence is associated. ("Report on the Cholera Epidemic in Northern India," by Dr. J. M. Cuninghame.) It is probable that the disagreement noticeable amongst the authorities quoted might be much reconciled by a precise definition of the word "contagion," which has been far from strictly employed, and is, with many, convertible with "infection." "Words," says Max Müller ("Lectures on Language," 2nd series, page 256), "without definite meanings are at the bottom of nearly all our philosophical and religious controversies, and even the so-called exact sciences have frequently been led astray by the same Siren voice."

I will now record my own experience during the epidemic of 1854, as to the contagiousness of the disease, which is highly confirmatory of the observations of Drs. Parkes and Cuninghame; and I am justified in stating that my lamented colleague, Dr. Filliter, entertained similar convictions.

Neither doctors, nurses, helpers, nor undertakers, who were constantly in contact with cholera patients, alive and dead, were attacked by the disease. The undertakers passed many hours in the dead-house daily, and I have seen them taking their meals there, as under ordinary circumstances. The medical officers were in the wards at all hours of the day, and I have passed as many as four hours daily in the cholera ward, which was specially set apart for the reception of patients, and was full, too full, for a long period. One of the helpers, named Strong, was on duty all day, and slept every night in one corner of the ward, that she might be ready in case of urgency.

A patient on the same gallery, but in an ordinary female ward, visited from curiosity the ward in which the cholera patients were located. This woman was attacked, being the only instance which occurred amongst the patients in this portion of the infirmary. She had been in for some weeks, having ulceration of the leg, and expressed great apprehension of cholera, after having witnessed the patients who were brought in. In consequence she was removed from the surgical ward, farther down the gallery to a medical ward, at the request of the nurse, and ordinary diarrhœa supervened some days after her removal. This continued for two or three days previous to choleraic symptoms. She remained untreated, avoiding to inform the doctor, "lest she should be sent to the cholera ward." Death took place eight hours after the access of characteristic symptoms, although I saw her directly, when summoned. Concerning this case, it may be fairly held that the exhausting operation of ulceration of the leg, great moral dread and depression and continued diarrhœa rendered her peculiarly favourable to the reception of morbid impressions, combined with which there existed a foul water-closet, which was much complained of by the patients in the ward, situated close to it, and the septic emanations from this source may be

regarded as the cause of the attack, without resorting to the aid of contagion as an explanation. The epidemic influence may be also presumed to have been present, as cholera was at the time prevalent in a court immediately behind the infirmary buildings. Two more cases, on the male side, afterwards appeared in another ward of the infirmary, far away from the situation of the female wards—the first, an old man, suffering from chronic vesical disease; and the other, the night nurse of the same ward. Both of these had previously had ordinary diarrhœa, and were feeble elderly persons, subjected to a close, ill-ventilated surgical ward, with an offensive drain in one corner, and the above court immediately in the rear. The old woman recovered.

Two cases occurred in the workhouse of St. Marylebone—one, a nurse, not attendant on cholera patients; the other, a man employed about the beds, and who possibly had been in contact with the bed-clothes and bedding of cholera patients; but several other men were also equally exposed, without any development of choleraic symptoms. I refer to, although I attach no importance to, the consideration of exposure in the above instance. The nurse mentioned had had diarrhœa for many weeks, and was a confirmed drunkard, living in a most confined part of the workhouse, poisoned by noxious influences, and not very far from the court formerly alluded to. The bed-man was also of irregular habits, had suffered for some time from diarrhœa, and was living under conditions of atmosphere similar to the nurse.

These were the only cases which occurred amongst the inmates of the infirmary and workhouse, and in all these three there was premonitory diarrhœa traceable to septic sources. There was also strong presumption of epidemic influence from the known existence of the disease in the neighbourhood, and only one of the three could be at all connected with direct exposure to contagion. I attribute the immunity enjoyed by the inmates generally to the thorough steps adopted for the establishment of cleanliness. From the cholera wards the evacuations were removed by the nurses as soon as discharged by the patients, which I regard to be a most important prophylactic measure in respect of the attendants. According to tradition, in a previous epidemic, twelve or thirteen cases appeared in one ward of the workhouse which abutted on the churchyard in Paddington Street, the remainder of the house remaining free from attack. My conclusion, therefore, is, that cholera, literally speaking, is not contagious; and when apparently so from communication with the sick, it is generally or invariably due to subjection to the same circumstances which originally infected the first individual; or to exposure to decomposing choleraic discharges from the person or garments of those suffering from the disease, as in the case of the woman at Malta (adverted to by Inspector-General Anderson), who developed the complaint after (dependent on?) wearing the unwashed linen of a patient. I do not regard the evacuations in cholera to be specific as a poison, but rather causing the disease—if they can do so—as might any other virulent septic material; and the choleraic dejecta may be assumed as highly prone to decomposition. I am convinced that mere contact of the body, or the breath of a patient suffering from cholera, cannot induce the complaint. The clothing of cholera patients should be disinfected or destroyed, as an assurance of safety. The limited contagiousness, if any, of cholera should be insisted on, and published to all concerned in its treatment, being of great importance to those attacked, as it tends to impart confidence to nurses and attendants, and thus render them more assiduous to the sick. Patients, if possible, should be removed from infected districts to other localities, as they are withdrawn from the influence of the original cause and are more favourably circumstanced for treatment. Dr. Cuninghame insists on the value of movement as a preventive of cholera, as facts point to a peculiar localisation of the disease.

On the whole, I consider the susceptibility of persons in health to cholera as very limited, unless the poison or

influence be of peculiarly malignant character, or there has been some previous privation, exhaustion, or indiscretion, as long fasting, over-fatigue, intemperance in food or drink; and if the history of cases amongst the better classes was ascertained and analysed, it would be in nearly all cases discovered that the attack follows bodily excess: and this, if the fact, explains the immunity of individuals in greatly infected districts. It is remarkable that during epidemics of cholera less deaths are noted on Saturdays and Sundays, owing to (?) freedom from depression, as there is rest from work, better food—wages having been paid—less water, and more stimulants taken. Galen observes, with truth, that epidemic influences, however powerful, are insufficient to induce disease without a peculiar disposition of the body to admit them; otherwise all, without exception, would be seized by the prevailing epidemic.

I have, to some extent, proved how rarely hospital attendants are attacked in the performance of their duties. If they are, they at first suffer from diarrhoea, which becomes malignant (cholera) from the predisposing nature of their office, confinement, irregular habits, watching, fasting, exposure to decomposing discharges and foul clothing of patients, and other sources of exhaustion, as well as sometimes to local epidemic influence. It is, therefore, not difficult to explain the causation, when doctors, nurses, and attendants are attacked, without seeking to maintain the contagiousness of the disease, *i.e.*, its communication by contact with those affected. These remarks closely coincide with the views of Mr. Whitfield, Resident Medical Officer of St. Thomas's Hospital, communicated to the Board of Health in respect of the epidemic of 1854, and with the more recent conclusions of Dr. Cuninghame.

Moreover, the disease appears at sea in ships far removed from every source of contagion, and it is frequently arrested on the confines of an infected territory which is in free communication with surrounding uninfected countries. Lastly, that cholera should appear to travel, or be conveyed, in the lines of human traffic and intercourse, might be expected, without resorting to the theory of contagion, as it is only amongst the human race that the conditions probably exist necessary or essential for its production.

(To be continued.)

WHAT IS MEDICINE?

By EDWARD LANE, M.A., M.D. Edin.

WITH the beginning of another year, when, not unnaturally, all reflective persons are disposed to sift and try themselves—to look backward as well as forward—it may not, perhaps, be thought so remarkable that we should be found putting ourselves such fundamental questions as the one at the head of our essay of the 23rd ult., and that which is to form the subject of our remarks to-day. Such periodical self-interrogations and examinations, eminently salutary to us as individuals, are fully as necessary to us as a profession. We desire to widen and strengthen the foundations of our noble art, hoping thereby to increase its usefulness, and the esteem in which it is held by a public making rapid strides in scientific education; and we cannot too carefully convince ourselves that we are practising it in the largest, the most liberal and truest spirit, in the way not only to accord with established usage, but to satisfy the requirements of independent and unbiased reason. No higher service, in our view, can be rendered to any profession by those who practise it. What, then, is medicine? Many will answer that it is a system whereby we are accustomed to heal diseases, or to attempt to do so, substantially by means of a set of medicaments from the vegetable and mineral kingdoms, and contained in an official repertory known as the *Pharmacopœia*. Such, we venture to say, is the popular

notion abroad on the subject, both in the ranks of the profession itself, and amongst the public. Nevertheless, it is a restricted, insufficient, and unsatisfactory definition. It is not true, as we hope—and if it were, we are sure it ought not to be. For what is the amplest and truest signification of medicine? Both etymologically, and in fact, it is the *Healing Art* (*Medicina—mederi*, to heal). Whatever, therefore, tends to heal, whether it be a drug on the one hand, or the return to the observance of the laws of health, which, having been violated, produced the disease; or whether it be simply the operation of mind upon mind through the mysterious agency of the nervous system—whatever be the proximate and ostensible cause of the restoration from sickness to health, that is medicine. Often enough, indeed very often, the malady with which a patient comes to us is secondary, not primary—a manifestation in one organ of a disease having its true seat and origin in another. He complains to us of a dyspepsia, and we discover on a little cross-examination that the organ really suffering, and primarily at fault, is an over-toiled brain, with which the stomach was only secondarily sympathetic through the medium of the nervous system, linked as each organ of the economy is with every other, as parts with a whole. And that being so, no one surely would believe that the rational treatment of such a case would be the same as if we had to do with a case of genuine disease of stomach in any of its forms. Or possibly the case may be one where we do not wish to call suddenly on any special organ reachable through the action of a drug within our knowledge, but where we are rather of opinion that it is more by a studied attention to the healthy performance of all the functions that the maintenance of their equilibrium, which in fact constitutes the state of health, can be expected or attained. In such a case our medicine may properly amount to nothing more than regulated exercise in good air, to simple diet, and perhaps moderate bathing. Or lastly, the case might be one where the malady, without amounting to mental alienation, is still one purely or chiefly of the mind, or perhaps springing from disordered moral emotions. It is evident that in treating mental and moral cases of this description, mental and moral medicines, and not material ones, are chiefly necessary, if we would practise our art intelligently and hope for success. We all remember Macbeth's exclamation—"Throw physic to the dogs, I'll none of it;" and again—"Canst thou not minister to a mind diseased, pluck from the memory a rooted sorrow?" This shows how fully Shakespeare, the "myriad-minded man," whose insight into the philosophy of life was quite as marvellous as the splendour of his imagination, had appreciated the true philosophy of medicine as well, three hundred years ago. And surely it is patent enough to every one who will but consider it in an independent spirit, the only risk being lest the force of habit and of tradition, together with lack of patient care, should warp the better judgment, and lead to a practice without discrimination and true science.

We assert, then, in answer to our own question, that whatever heals, or tends to heal, is indeed medicine, whether it be an adjunct to the *vis medicatrix naturee*, in the form of one of the drugs of our *Pharmacopœia*; whether it be merely the practice of what has been impressively called "hygienic medicine," as denoting the systematic use of the hygienic agencies in their combination; or whether, finally, it consist even only of moral advice. There can be but one gauge and touchstone for all. Do they perform for the patient what he requires—do they cure him? If so, they constitute medicine in the largest and truest sense, and nothing, we are persuaded, will more tend to rescue our profession from a slavish routine and elevate it to a position of dignity and public confidence, than the recognition of the fact. Indeed, if we were to offer a hint to the young physician, fresh from the lessons of the schools, and eager to put them at once into active operation, we should say, "Do nothing rashly; be thoroughly sure of your diagnosis before you think of prescribing; be content to do rather

too little than too much, determining above all things that if you cannot benefit, assuredly you will not injure your patient, in accordance with the maxim of the great Sydenham—*primum est ut non nocere*. And generally: while eager to have the experience of your seniors, and to treat it with deserving respect, learn also from the beginning to rely systematically on yourselves, both as to facts and the deductions to be drawn from them. Keep the inlets to your intelligence always open to truth, come from what quarter it may, without favour or bias. Be as far as possible perfect in your knowledge of the routine of your profession, yet always ready to re-learn your practice from wider and better theory, remembering with Bacon that 'they be the best physicians who, being learned, incline to the traditions of experience; or, being empirics, incline to the methods of learning.' What might not be hoped from the medicine of the future, if the rising generation were to practise it largely after that method and in that spirit!

ON THE PROBABLE EMPLOYMENT OF ANÆSTHETICS IN ANCIENT TIMES, ESPECIALLY IN SCOTLAND AND IRELAND. (a)

By THOMAS MORE MADDEN, M.D.

THE author of this paper commenced by observing that, although there were few subjects of higher literary importance to medical men than the history of those discoveries which have tended materially to the alleviation of suffering or the prolongation of life, the number of such medico-historical investigations brought before the Society was very small when compared with what are generally regarded as more practical contributions. Therefore, when honoured with a request to read a paper there, it occurred to him that the novelty and interest of the subject might induce the Society to extend their kind indulgence to the following notes on some of the earliest attempts to ensure insensibility to pain by anæsthetic agents, which he had collected several years previously, but which he was now unavoidably prevented by lack of time from revising or enlarging so as to render more worthy of the acceptance of the Society. Researches into the history of modern improvements in medico-surgical art generally bear out the observation of the inspired writer that "all novelty is but oblivion;" and every day we find new proof of this in the revival of ancient arts under an improved form as modern discoveries; for, as Lord Bacon well expressed it, "the river of Lethe runneth as well over as underground," and certain it is that the student of the now neglected works of the ancient medical writers will find many striking coincidences between so-called recent inventions and the long-forgotten ideas of our predecessors.

This topic was one which Dr. More Madden had elsewhere discussed, and had shown that many of our modern surgical appliances, particularly those used in obstetric and gynecological practice—the midwifery forceps, the vaginal speculum, the uterine sound, and *porte caustique*, and the employment of sponge tents, and nitric acid in uterine diseases (on the supposed invention or application of the four latter of which, in our own time, some have risen into reputation and fortune) were all long ago well known, but in the course of time had fallen into that desuetude and oblivion which will as surely one day overtake our own boasted inventions, and from which they may in due course be again resuscitated and claimed by future discoverers.

In proof of the antiquity of the use of anæsthetics in surgical practice in Scotland, Dr. More Madden quoted the following passage from Jocelyn's "Life of Kentigern, or St. Mungo, Patron of Glasgow," a work written in the twelfth century, between the years 1175 and 1199:—

(a) Abstract of a paper read before the Medical Society of the College of Physicians, Dublin.

Constat nihilominus nobis multos, sumpto potu oblivionis quem physici lethargion vocant obdormire; et in membris incisionem, et aliquotiens adustionem et in vitalibus abrasionem perpeços, minime sensitisse, et post somni excussione, que erga sese actilata fuerant ignorasse.

This life, which is edited from a unique MS. in the British Museum, Cott. Vit., c. viii., 12th century, was written by the celebrated Jocelyn, of Furness, the biographer of St. Patrick, and is dedicated to another Jocelyn, Bishop of Glasgow.

Dr. More Madden then endeavoured to show that the essential components of this *potu oblivionis quem physici lethargion vocant* was the juice of the *Mandragora officinalis*. In support of this view he cited a remarkable passage from a Celtic *Materia Medica* of the twelfth century, evidently taken from Pliny's account of this long disused acro-narcotic poison, which concludes with the words—"*Bibitur et contra serpentes et ante sectiones punctionesque ne sentiat; ab hæcatis est aliquis somnum odore quærisse.*" Thus, if surgical anæsthesia was known in Scotland, and if the means by which it was produced and the writings in which it was treated were known to the ancient Irish physicians at the same time, both of which are proved in this paper, we may, he observed, reasonably conclude that the same practice was probably known to our ancestors in the healing art in this country.

The anæsthetic properties of mandragora are also spoken of by another writer, repeatedly quoted by the author of the ancient Irish manuscript referred to by Dr. More Madden—namely, by Isidorus, who says: "*Cujus cortex vino mixtus, ad bibendum iis datur quorum corpus propter curam secandum est, ut soporati dolorem non sentiant*" (C. 333). The late Dr. Snow (in his work, "On Chloroform and other Anæsthetics," p. 2, London, 1858) quotes Apuleius, who speaks thus of mandragora: "Further, if any one is to have a limb mutilated, burnt, or sawn, he may drink half-an-ounce with wine, and whilst he sleeps the member may be cut off without any pain or sense." ("De Herbarum Virtutibus," c. 131). Dr. More Madden, however, observes that in the earliest version of the "Herbarium" of Apuleius with which he is acquainted—namely, the Saxon copy, published by direction of the late Master of the Rolls, and the original transcript of which was probably made about the year 1050—the passage cited by Dr. Snow does not occur.

Mesmerism, which has been long used as an anæsthetic agent of great power in India, where Dr. Esdaile, some time Presidency Surgeon at Calcutta, performed no less than 261 operations under its influence, was introduced with less success into England as a novelty about thirty years ago by Dr. Eliotson. It seems to have been utterly forgotten, however, that animal magnetism, or mesmerism, had of old been a well-known practice in Ireland, and has been fully described by Dr. R. R. Madden in a paper published in the *Dublin Quarterly Medical Journal* for August, 1847; and in Dr. R. R. Madden's paper a remarkable account may be found of a ceremony practised by the pagan Irish as far back as the year 50 A.D., which appears to have been almost identical with that now employed by animal magnetists for the purpose of throwing their patients into the mesmeric trance.

In Middleton's tragedy of "Women Beware of Women," written in the middle of the seventeenth century, we find the following mention of surgical anæsthesia as a familiar idea:—

HIPOLITO. "She shall never know till it be acted:
And when she wakes to honour then she'll thank me for it.
I'll imitate the pities of old surgeons
To this lost limb; who, ere they show their art,
Cast one asleep, then cut the diseased part." (a)

Sprengel, in his "History of Medicine," published long before surgical anæsthesia was a recognised fact, in speaking of operations, quoted Théodoric, who advised the administration of opium and hyoscyamus before ope-

(a) Middleton, "Women Beware of Women," Act IV., Scene 1. London, 1657. See also *Notes and Queries*, 2nd series, vol. i. (May, 1856), p. 351; vol. vi., p. 470; and vol. vii., p. 127.

rations for the purpose of throwing the person to be operated upon into a state of unconsciousness, from which, after the operation, he aroused them by giving vinegar and fennel.

Dr. More Madden further cited a number of other authors to the same effect, and briefly referred to the history of anæsthesia from the earliest period until the time when, by the introduction of ether and chloroform into surgical practice, that great object of relieving pain at will, which the ancient physicians of every land had sought to obtain by less efficacious and ruder means, was at last accomplished.

ON A TUMOUR OF THE PAROTID REGION. (a)

By ANTHONY CORLEY, F.R.C.S.,

Surgeon to Jervis Street Hospital.

MR. PRESIDENT,—The occurrence of a primary encysted subcutaneous cancerous tumour of the parotid region is an event of sufficient importance from a surgical and pathological point of view to merit its being brought under your notice. I trust that the case which I am about to relate and the few remarks I make on it may evoke that judicious criticism and exhibition of information and experience which usually confer such value on the discussions of this Society.

John Doyle, a healthy, able-bodied sea-faring man, æt. 34 years, was admitted into Jervis St. Hospital in the beginning of last November. He complained of a tumour in the parotid region, the appearance of which is very well shown in the photograph, taken shortly after his admission. He stated that he had first noticed it as a small kernel, about the year 1860, and that it had continued to grow very slowly up to about three years ago, since which time its progress had been more rapid. The tumour, to the touch, was extremely hard and dense, stretching up in front of the ear nearly as high as the horizontal root of the zygoma, and behind the ear, encroaching on the mastoid process. Between these points the lobe and lower part of the concha were displaced and pushed upwards. The inferior extremity of the tumour extended about two inches below the angle of the jaw. The same part of the growth seemed the most movable, and on all sides, especially the posterior, there was a well-defined border. A portion of the most projecting surface presented a glazed and smooth appearance, and was covered with the ramifications of minute but visible blood-vessels. This patch of surface was plainly cicatricial, and the patient explained its existence by stating that about ten years ago he applied to it what he was told was a "cancer paste," which destroyed a portion of the skin, but had no effect on the tumour. Another rather remarkable feature in the case was that he had no less than fourteen atheromatous tumours on his scalp, varying from the size of a large pea to that of half a billiard-ball. These he gave me at first to understand had existed previous to the appearance of the parotid tumour; but in an interview after the operation he was able to recollect that they appeared about the time he had applied the paste, that is, when the tumour had been four years growing. Being alarmed at the recent progress of the tumour, he had made up his mind to have it removed, and accordingly, on the 6th of November last, with the approval of my colleagues, I proceeded to extirpate it. I may truly say that I never attempted an operation with a deeper sense of responsibility than on this occasion, even though I thought it not improbable, from the existence of the numerous wens, that it was an atheromatous cyst. During the removal of smaller tumours I have seen Steno's duct divided, and the portio dura severed, and I have known the external carotid artery to be cut; and, though salivary fistula, Bell's paralysis, and secondary

hæmorrhage are very interesting pathological conditions in themselves, and generally susceptible of cure, still they are not by any means desirable accidental results of an operation, and the possibility of their occurrence does not tend to beget extra confidence in an operator. The manipulation of the proceeding was, at first, very slow, owing to my wish to avoid prematurely opening a cyst; but when, as reaching the part behind the ear, the encapsulated character of the growth became apparent, I at once proceeded rapidly with the extirpation, substituting my forefinger for the knife and director, and I soon succeeded in taking out the mass completely, although the deep process gave me some trouble. The only connection which I was obliged to cut was a short fibrous process at the upper end, and one small artery alone, about the same place, required ligation. There was no bleeding to signify, and the gaping cavity between the jaw and mastoid process could be thoroughly examined both by sight and touch. The deep process of the tumour went in considerably beyond the styloid process of the temporal bone, which could be plainly felt, and the whole parotid region could be explored without detecting the trace of a gland. At the deepest part a strong pulsation was visible, probably of the internal carotid artery. I may remark that Steno's duct, the external jugular vein, the external carotid, and the facial nerve were not seen during the operation, nor was I too inquisitive in seeking for them. The patient has now left for his home, with the wound completely healed, and only a slight fulness to mark the former site of the tumour. Of the operation I can say but little. Although so easily taken away, it had very deep connections—so deep, in fact, that a friend of mine who saw it facetiously remarked, "that had it stretched any further inwards, it might have been easier to take it out from the other side." Yet ready removal was more a matter of good fortune, depending on its encapsulated character than on exhibition of surgical skill. There are, however, some points discovered during the operation that lend much interest to the subsequent examination of the growth. First, it was a tumour not ulcerating outwards, or in any way connected with the cutaneous surface; secondly it was quite separate from the parotid gland, which it had evidently displaced or obliterated by its growth; thirdly, it was as distinctly encysted or encapsulated as a fatty tumour; and fourthly, it had enjoyed a growth of fourteen years without involving or infiltrating any of the surrounding tissues. Now, with reference to the pathology, you are well aware, Sir, that of late years the attention of pathologists has been specially directed to the investigation and discovery of the particular histological elements from which tumours—especially those dangerous to life—have their starting point. Until comparatively recently the views of Virchow as to the common origin of different kinds of tumours from connective tissue elements were generally held. When, however, the essential differences between the two principal groups of dangerous tumours—namely, the sarcomata and the carcinomata, began to be clearly understood, pathologists were prepared to receive the views enunciated by Waldeyer, Billroth, and their followers, that sarcoma and carcinoma differ in the elements from which they start, and that the latter can only have an epithelial origin. There are two other more recent views as to the origin of true cancer, but as they are only modifications of the connective-tissue theory, I shall do no more than mention them. The first of these is Küster's, who suggests that the elements of cancer arise in, and are produced by, proliferation of the endothelial cells lining the ultimate extremities of lymphatic vessels, and Mr. Woodward, the distinguished American pathologist, considers that the white corpuscles of the blood are the starting points of the morbid process. As both endothelial cells and white corpuscles are derived from the same source as the connective tissue—namely, the middle layer of the embryonic germinal membrane, we have practically but two theories before us. We may hold with Virchow that carcinoma has a connective tissue origin, or with Waldeyer that it

(a) Read before the Surgical Society of Ireland, December 11. Discussion will be found at page 9.

must have started from some structure possessed of epithelial cells. It is only fair to state that recently Virchow's views have had the support of such accurate and skilled observers as Cornil and Ranvier, and I bring forward this case as a contribution bearing on the point at issue. It is almost with regret I am forced to confess that it is a strong argument against the epithelial origin of carcinoma. Waldeyer's theory has much to commend it; there is at once a simplicity and completeness about it; and, when pushed to its full extent, an importance clinically that makes it almost a matter of regret that it should be proved erroneous. Thus every normal tissue of the body is known to have its origin from one or other of the three layers of the embryonic germinal membrane, and the epithelial surfaces can only spring from the outer and inner layers respectively of this membrane, while all the other structures arise from the middle one. If, therefore, we could say from which of these any normal structure found in the body arises, it would be possible at once to determine in which of the two classes under consideration we should place a tumour starting from that structure. The importance of this diagnosis can scarcely be over-estimated. It is true that the difference in malignancy between sarcoma and carcinoma is only one of degree, still that degree is a considerable one; and as it seems to be now almost universally admitted that, whereas the cancers prove secondarily infecting through the blood-vessels and lymphatics, the sarcomatous element through blood-vessels only, the prognosis after removal of the latter would be considerably more favourable than in the case of the former. It would be most satisfactory to be able to feel that if a tumour arose primarily on some acknowledged connective tissue, such, for example, as bone whose cellular elements are direct lineal descendants of the original cells of the middle layer of the germinal membrane, it must be of necessity the semi-malignant sarcoma, that it cannot be the truly and intensely malignant carcinoma, that it is so much the less likely to be attended by secondary infection, or its removal followed by recurrence. The tumour which I submit to you has no connection with the cutaneous epithelial surface, none with the ducts of the parotid gland—is unquestionably an example of an epithelioma, as the specimen under the microscope clearly shows, and as it must have had an origin other than from an epithelial surface, we must regard it as a fact in support of the connective-tissue origin of cancer.

Transactions of Societies.

THE SURGICAL SOCIETY OF IRELAND.

The Society met on the evening of the 11th December, Dr. E. HAMILTON, Vice-President, in the chair.
Mr. CORLEY read a paper on

TUMOUR OF THE PAROTID REGION,

which will be found at page 8.

In the discussion which followed,

The CHAIRMAN observed that the case was most instructive, and one of the most interesting points connected with it was the great length of time the tumour existed without manifesting any malignant form, so to speak.

Dr. STAPLETON was present at the operation, which caused a great deal of anxiety to all who had assisted at it. The tumour exhibited that evening was not half the size it was when extirpated. He had never seen an operation better performed. They could have no idea from the specimens before them of the enormous attachments that ran in behind the angle of the jaw. He was able to put his finger into the cavity caused by the removal of the tumour, but without coming to the bottom of the space out of which the tumour had come. The man had recovered remarkably well so far. As the cancer had not escaped through the capsule and con-

taminated the neighbouring parts, they had reason to hope that the disease would not return.

Dr. WHARTON thought the observations of Mr. Stapleton as to the constitution of this tumour were correct. If a tumour existed in the parotid region for so many years the inference to be drawn was that it was not malignant. He could sympathise with Mr. Corley as to the difficulty of the operation, for he had had himself a case of a similar kind, and had experienced great difficulty in removing the tumour. The enormous and deep attachments, the extent of the fangs, which would almost cut a man's finger, increased very considerably the difficulty of removing a tumour of this kind, and if to this were added the anatomical situation of the tumour, the surgeon was naturally very anxious about the result. In the case which was under his care, his colleague, the late Mr. Maurice Collis, on examining the tumour, said it had been a disputed point among surgeons whether the parotid gland could be removed. It appeared from the case detailed by Mr. Corley that it could be removed. The non-contamination of the glands in the neighbourhood was a very important element in considering the question of the malignancy or otherwise of the tumour, and taking all the circumstances of the case into consideration, he thought they might come to the conclusion that the disease in itself was not malignant.

Mr. STAPLETON did not say positively that the tumour was not malignant, but that the neighbouring parts, being uncontaminated, they had good reason for hoping that it was not.

Professor STOKES said there were two very interesting points connected with this remarkable case—in fact, two circumstances which rendered the case almost unique. He had hitherto been of opinion that epithelial tumour occurred on the muco-cutaneous or cutaneous surfaces; but here was a case in which the tumour originated not in those structures. That was a novel occurrence in a case of epithelioma, for he assumed that after the careful examination made by Dr. Corley and Professor Purser there could be no doubt as to the accuracy of these observations. The other peculiar feature in the case was the occurrence of this malignant growth enveloped by a capsule. The situation of the disease, and the fact of its being enveloped by a capsule, rendered it a case of remarkable interest in both a surgical and a pathological point of view. A gentleman who was present at the operation said there was not a particle of the parotid gland present in any section of the tumour. Neither the facial nerve nor the external jugular vein was touched, nor were any of the large veins in the slightest degree included in the tumour, nor was there any duct in the tumour. It was entirely capsulated, and therefore they might conclude that it was not part of the parotid gland. A member said that some eight or nine years ago he removed a tumour similar in character, but not one-third of the size of that exhibited by Dr. Corley. In that case it had absorbed the greater part of the parotid gland; it also had a capsule, and turned out very much as Dr. Corley's had done. After the wound healed the patient went to his residence in the country, and three weeks afterwards returned with a collection of fluid, and the integument stretched over it very thin indeed. A small trocar with a canula was introduced from the inside of the mouth into this secretion, and after ten days there was an artificial duct established, and the secretion went into the mouth ever afterwards.

Dr. HENRY KENNEDY said the histology of the tumour involved the question, how far the microscope was superior to the naked eye in enabling them to make a diagnosis? This subject was discussed some years ago in the French Academy of Medicine, and opinion on the question was much divided. The result of that discussion shook his confidence in the microscope. He was borne out by many in this view, and by none more so than by the late Professor Smith, who invariably said that the naked eye was a much better test of the malignancy or non-malignancy of tumours than any microscope. He (Dr. Kennedy) remembered on one occasion taking a tumour, at the request of Dr. Law, to the late Professor Houston, and that gentleman said, "Unless you give me the history of this case I will not, as a microscopist, say whether it is malignant or not." Anyone who had read the recent "Transactions of the London Pathological Society" could not fail to be struck with the fact that this particular form of investigation had, as it were, run riot. There were a number of new terms and titles given to structures, with which they were all familiar already; but the microscopists did not say whether those structures were malignant or not. Of the two means of investigating, the naked eye, he believed, was superior to the

microscope. The circumstances of the present case were all against the fact of the tumour being malignant.

Dr. BENNETT could not allow the observations of Dr. Kennedy to pass without making some remarks upon them. He laboured under a mistake when he stated that the opinion of the late Professor Smith was in favour of the naked eye diagnosis of the nature of tumours. On the contrary, he (Dr. Bennett) distinctly recollected that on the last occasion this matter arose in discussion between himself and Professor Smith, the latter expressed his deep regret at his inability to investigate matters microscopically, and he placed implicit faith in the most recent microscopic investigations, more especially those of Virchow. In reference to the classification which Dr. Kennedy wished to revert to, of malignant and non-malignant, it might be treated by the observation of Virchow himself, who said that they might as well, in treating of botany, classify plants as poisonous and non-poisonous.

Mr. H. GRAY CROLY showed a drawing of a parotid tumour which he had met with in his practice. As to the diagnosis of parotid tumours, all surgeons were prepared to look on them at first as being benign growths. He had removed more than one, and none of them had been malignant. So far as the examination by the microscope had gone, they should all feel satisfied when two experienced surgeons had examined it, that this tumour was not of a benign nature, if they were to believe in the microscope. The tumour of which he exhibited a drawing was growing, like Dr. Corley's case, for fourteen years. The lower part of it commenced to bleed, and one might at first think it was taking on a malignant aspect; but the bleeding arose merely from the dependent nature of the tumour. As to the diagnosis of these tumours by the naked eye and the microscope, he had had many tumours examined microscopically, and the diagnosis was not always certain. On one occasion the late Mr. Maurice Collis expressed his opinion, from microscopic examination of a large tumour in the thigh, that it was benign. In twelve months afterwards the tumour recurred in the groin, and killed the patient. The difference of opinion might often arise from different portions of a tumour being examined by different gentlemen. He remembered the case of a tumour in a very young child in which he refused to operate. Another surgeon was consulted, and from the result of a microscopic examination of what was got out of the tumour by the needle, he said he would cut it out; but after seeing him (Mr. Croly) he declined to do so; and the tumour afterwards presented all the appearance of fungus hæmatodes, which he from the first suspected it to be. The needle had run into some of the fat cells, and some of the fat which came out being placed under the microscope led to the belief that the tumour was a benign one. He was satisfied from Dr. Corley's description that this was an exceptional case, if not an unique one, from having a capsule, which was unusual in cases of cancerous tumours. He should like to know at the end of a year how the case had resulted. No society could undertake to decide a case of this kind until they had learned the subsequent history of the patient; and for himself he never made up his mind whether a tumour was malignant or benign until he heard, after a couple of years, how the patient was getting on.

Dr. CORLEY, in reply, said it appeared to him that the difference of opinion expressed as to the character of the tumour was a good excuse for his having brought the case forward. Mr. Wharton's view that the tumour was non-malignant because of its being encapsulated was, no doubt, a strong one as regarded slowly growing tumours. In rapidly growing tumours, which increased so rapidly as not to have time to contaminate the surrounding tissues, they were occasionally found encapsulated. The important question, then, was, whether this true carcinoma originated in the connective tissue or not. Mr. Wharton said he considered it a tumour of the gland. With reference to that suggestion it could scarcely be conceived possible for a tumour of the gland to grow in such a way as to carefully exclude from its substance the external carotid artery, the external jugular vein, and the facial nerve. Mr. Stokes observations contained the pith of the case—namely, that it was a cancerous tumour growing subcutaneously, and without any connection with the gland. With respect to the microscope, he assured Dr. Kennedy that the study of that instrument had made such progress of late that some three years ago, when he had occasion to do some histological work, he found himself so completely behind the times that he had to begin the study of it anew. If one wished to study the researches of the modern German investigators in that line, he would find that the education given fourteen

years ago was sadly behindhand. With reference to the recurrence of the tumour, he could only say that the man had left with a small lump below the ear, which might be the displaced parotid, or the contracted capsule, or the nucleus of a new growth; and the prognosis he gave was that the tumour would probably not recur, but he could not say for certain. Mr. Croly's case was more of a glandular form than his, and did not bear on the question here of whether these tumours grew from the epithelial surfaces or the connective tissue. A case such as the present, which was a cancerous tumour growing from the connective tissue, was an important one as bearing on a question still *sub judice*. The tumours on the scarp were common retention cysts, and had no connection with that in the parotid region. They were apparently hereditary, as for two or three generations many members of the patient's family had been affected with them.

OBSTETRICAL SOCIETY OF DUBLIN.

THE second meeting of the present session took place on Saturday, December 12th.

Dr. LOMBE ATTHILL, President, in the chair.

Dr. McCLINTOCK made a communication to the Society on the subject of the

MORBID RETENTION OF THE DEAD OVUM.

In the course of his observations, Dr. McClintock said that under the head which he had chosen as the title of his paper he included all those cases where the ovum or part of its involucre are retained *in utero* beyond some days after the death of the embryo. These cases were not very uncommon, and formed a group possessing great interest for the practitioner, the pathologist, and the medical jurist. He described very succinctly the grounds of diagnosis and the general principles of treatment of these cases, and specially insisted on their great importance viewed from a medico-legal standpoint. With reference to the length of time which the dead ovum may be retained in the uterus, his opinion, corroborated by that of Velpeau, was that the presence of the devitalised ovum is not tolerated beyond the ninth month of pregnancy. In one of the cases related from his own experience, the ovum, blighted at six weeks, was not discharged until the beginning of the ninth month of utero-gestation. On the subject of diagnosis the point of paramount practical importance to determine was, whether the patient carried a living ovum or not. In addition to the history of the case, the symptoms upon which he placed most reliance were enlargement of the uterus, patulencia of its orifice, recurring sanguineous losses, menorrhagia and fetor of the discharge, though he admitted this last symptom to be as often absent as present. Where the hæmorrhages were not severe he rather counselled an expectant line of treatment, at the same time keeping the discharge in check as much as possible; but that if active interference was required, they could dilate the os uteri with laminaria or sponge tents, and thereby gain access to the interior of the womb and remove the offending matters within by forceps or douching. He showed to the Society an ovum which had been expelled by a lady about seven months after conception, and five months from the time that its vitality had ceased.

Dr. CHURCHILL said that he had met with about half a dozen cases similar to those alluded to in the admirable paper of Dr. McClintock, and although he had no actual data to fix the period of retention of the ovum, still they were retained sufficiently long to give rise to great difficulty—and really there was much greater difficulty in practice in these cases than could be imagined from having them described in a paper. It was not easy to resist the one or two disturbing influences which were always found in these cases. A lady told them that she was quite certain she was not pregnant—a remark that could not fail to have some influence on them. He recollected the case of a lady who consulted him with reference to an abdominal tumour. She declared that she was not pregnant; there was regular menstruation, and an examination by means of a sound led to no discharge of blood or water. Subsequently, however, she expelled a blighted fetus of about four months' growth. Another case he had seen in consultation with Dr. Pollock. It was one of menorrhagia. The lady had lost a good deal

of blood, owing, as she said, to her having miscarried some three or four months previously. She was so positive of having miscarried that he (Dr. Churchill) thought probably she was right. He found the uterus enlarged, but not very much so, and a gaping-mouthed womb. For some time the menorrhagia diminished, but subsequently she had a furious attack of it; and he agreed with Dr. Pollock to plug and give her a little rye. When Dr. Pollock went to remove the plug he found something protruding from the os uteri, which turned out to be a blighted ovum. He (Dr. Churchill) did not know a case in which it was more difficult to give a positive opinion. Fortunately, the treatment was not so uncertain, because, in the first place, they must restrain the loss of blood. That effect would be produced by plugging, and probably the best remedy for menorrhagia would be the best remedy in a case of the nature under discussion.

The PRESIDENT said they were quite at sea with respect to the length of time a dead ovum might be retained, and he did not think there was sufficient data to clear up that point. He had twice been able to come to a pretty fair conclusion as to the period at which an ovum might be retained after its death, and both were comparatively short spaces of time. One was a lady who had been in the memorable Abergele accident, she being then five months pregnant. At the time of the occurrence she felt no remarkable effects, but afterwards did not increase in size. Thirteen weeks passed without any abnormal symptom; but at the end of that time profuse hæmorrhage set in, after which she was delivered of a dead fetus, which was no larger than it should have been at the time of the accident. In that case, therefore, the fetus had been retained thirteen weeks after its death. In the other case a lady came to consult him who said that she had aborted within eight weeks of her time for confinement. Recently she had had a scanty menstrual period, and suffered a good deal of pain at the time. When he saw the uterus it was considerable in size; but he did not make any examination with the sound; prescribed for her, and told her to come to him after the next menstrual period. On seeing her again she told him she had since menstruated, this time rather profusely, and suffered a good deal of pain. On examining her uterus he found that it was not enlarged. He introduced a sound, and a few days afterwards she expelled a small ovum. There was no doubt that several months elapsed between the time he passed the sound and the period when she thought she had aborted. In these cases the questions both of diagnosis and treatment were involved. If the symptoms of which she complained were due to the retention of the ovum, the duty of the medical practitioner was to get rid of it. If, on the other hand, there were other unhealthy conditions, they should have been treated. Of course they all knew that portions of the ovum might be retained for a considerable time. He did not think a fetid discharge was common in these cases.

Dr. J. A. BYRNE said that Dr. McClintock had touched upon a very important branch of obstetric practice. It was his (the speaker's) opinion that, as a general rule, ova were not aborted for a considerable time after the ovum perished. It was generally, however, taught in books that the ovum, when it had perished, was very soon afterwards expelled. His experience was not so. He thought they might fairly conclude that the ovum remained much longer *in utero* than was generally supposed, as a rule. If they took one hundred cases of aborted ova and examined them carefully, they would find no trace of vesicular degeneration; in fact, such instances were exceedingly rare.

Dr. DENHAM thought that the author of the paper had said all that was possible on the subject. It was one of the deepest practical importance, and one that every day came across their path and gave them a vast amount of anxiety and disappointment. He thought the Society was deeply indebted to Dr. McClintock for having brought the subject under observation. There were several points of interest connected with it. Whatever led to the safety of their patient should, of course, be their first and great object. The second was the life of the fetus, if it could be preserved; but that was a doubtful point with respect to the practice, whether the fetus is really alive or not. He thought these cases were surrounded by a greater amount of annoyance and perplexity than any others which crossed the path of the practitioner. If they could come to the conclusion that the fetus had perished, they then had no doubt as to their line of practice; but he thought it was most difficult to determine the question. He knew of a lady in a

state of pregnancy who had walked to such an extent while staying at Killarney that she brought on a menstrual discharge. She returned to Dublin, and remained under his care for two months, during which time she lost a vast amount of blood in clots and otherwise, and yet after all that the fetus survived, and she went on to the full time, and was safely delivered of a child. He knew another lady who, in stepping suddenly out of a carriage, felt conscious of something having given way. At the time of this occurrence she was not more than six weeks pregnant, and aborted without the loss probably of more than a teaspoonful of blood. Now, however, that lady was very ill: one day she had a severe hæmorrhagic discharge; another she was in a good deal of fever; and altogether, he found hers a most perplexing case.

Dr. McCLINTOCK, in closing the discussion, said the debate had certainly brought before them the fact that cases of this kind created a good deal of anxiety and suspense both to the patient and the practitioner, which suspense was often prolonged for weeks. He thought the tendency of Dr. Denham's observations was to confirm the statement that he (Dr. McClintock) had made in the body of his paper. The whole question narrowed itself into this: Does the patient carry a living ovum or not? If all the evidence led them to believe that the ovum was dead they were at once taken out of a difficulty, as the treatment was very plain and simple. On the other hand, as in the instance Dr. Denham had mentioned, there was very great difficulty when they approached the case of a woman who had been losing blood for weeks and months. Under such circumstances they might reasonably infer that it would be impossible that normal pregnancy could go on, or that the fetus could be living while that constant drain was upon her. And yet they probably all had seen occasionally similar cases. Many, doubtless, recollected an instance of this kind where six or eight experienced accoucheurs could not decide whether a woman was pregnant or not, and the result of the treatment they resorted to was the expulsion of a living ovum the next day. Unless the evidence was conclusive, they would not be justified in adopting means that would bring about a miscarriage, for then they might be placed in a very awkward position. The principle that would actuate him in a case of the sort, where he could not decide, would be that he would be free to adopt any treatment he liked. Still, however, if the hæmorrhage was so great as to endanger the woman's life, he would give ergot, or plug the vagina (which was a measure often very apt to induce abortion), or introduce a sound. But in a case in which he was not clear whether the fetus was living or not, he confessed he would be very slow to use the sound. He thought, in conclusion, that the weight of evidence went to show that a fetid discharge was a very rare symptom.

Dr. MACAN read a paper on

A CASE OF SPONTANEOUS AMPUTATION IN UTERO.

The left forearm was the part amputated; the seat of the amputation was just below the insertion of the biceps. The child was healthy, and well-formed in all other respects. The amputated portion of the limb was not found, though looked for. Dr. Macan reminded the members of the Society that it was Montgomery who first gave any rational explanation how such a deformity could be produced. His theory was that such amputations were caused by bands of organised lymph, themselves the product of inflammation—that these bands became twined round the foetal limb at an early period of intra-uterine life, and that as the limb grew these bands gradually became tighter and tighter, till finally all nutrition was cut off from that portion of the limb which lay below the ligature, and it dropped off. Before Montgomery this deformity had been ascribed to the effects of gangrene. As to how these ligatures become applied round the foetal limb Montgomery gives no explanation. Dr. Simpson noticed the curious fact that in some case there is an attempt at the rudimentary reproduction of the amputated limb on the face of the stump, and gives two cases in illustration, in which rudimentary fingers with nails attached were plainly seen on the face of the stump. Some have thought that such amputation could be caused by the cord. Any compression of a limb by the cord sufficient to cause arrest of nutrition in the limb would almost certainly so interfere with the circulation in the cord as to lead to the death of the fetus. It may, however, perhaps happen in cases where one artery of the cord is compressed or where the Whartonian jelly is very firm and plentiful. That the left side of the body is the one more generally affected, Dr. Macan thought might perhaps be explained by the fact that the foetal movements, as

deduced from the direction in which the cord is generally twisted, is usually from left to right. Scanzoni thinks that in some cases, as in Prof. Martin's case, especially where the child is well-formed in other respects, the cause of the lesion may be fracture. Where the deformity is symmetrical he thinks it could hardly be caused by adventitious bands formed by chance. Schröder thinks that these bands are caused by adhesions between the amnion and the foetal skin during early foetal life, the predisposing causes being too late or too scanty secretion of the liquor amnii. Fürst, in the 2nd vol. of the *Achiv. für Gynäk.*, gives three theories to account for their production, and himself inclines to the belief that they are caused by some interference in the due formation of the sac of the amnion with "plastic adhesion" of contiguous parts.

Dr. MACAN noticed the fact that if these bands, instead of encircling a limb, were only inserted into it, and thus produced a constant traction in the same direction, they might lead to the formation of other deformities, such as crooked limbs, dislocations, &c., &c.

observer remarking that there are some parts of the corpora striata which correspond to other points in the same hemisphere. Braun has endeavoured to weaken the reasonings deduced by Dr. Ferrier from his experiments by observing that when the cortical surface of the brain is sliced away weak currents applied to the white fibres will produce the same effect as when the grey matter is irritated.

The Colleges of Surgeons and of Physicians of London have not done anything very remarkable during the past year in the way of facilitating the attainment of one curriculum and diploma which shall in some degree resemble the licence to practise given in Germany.

Our nineteen Examining Boards still continue constant to but a few ideas; the first, of course, being that they shall try to exist as long as possible; and the second, that they shall offer as much opposition as they can to any change, since changes of all sorts are apt to hasten their doom.

During the past year the College of Surgeons was applied to by Mr. Critchett to grant an examination to such women as could prove that they had been properly instructed in anatomy, physiology, and other parts of a medical student's curriculum, and the reply was in the negative. Meanwhile, in the United States, 600 women are said to practise medicine; and in Russia the first fourteen women surgeons have just passed their final examinations and entered the profession.

Vivisection has been greatly revived in the last year, and, in consequence of this fact, doubtless, much discussion on an important question in ethics has taken place. On the one hand, it is clear that by operating on the lower animals, without the most solicitous care for their feelings, we seriously lower that high moral tone which should obtain among the class of the community which devotes itself to alleviating suffering and disease; and there can be little doubt that in several countries on the Continent there have been myriads of cases in which downright heartlessness and cruelty have been exercised on horses, dogs, cats, and, above all, on rabbits, guinea-pigs, and frogs. The school of Alfort, in France, has often been cited as a frightful example of such practices. On the one hand, it is clear enough that there are several difficult points in physiology which require us to summon to our aid the experiments on the lower animals. When such is the case, the experimenter is bound in honour, and ought to be bound by the fear of legal prosecution, to take the utmost care that some anæsthetic be given to the poor animal chosen for the experiment. If he do not take this care, he will inevitably lower his own *morale*, and by doing so tend to make his profession less esteemed by the world at large as a noble and tender-hearted calling.

In practical surgery the year 1874 has to chronicle the plan of bloodless operations recommended by Professor Esmarch, and that of elastic ligature, brought forward by Dr. Dittel, of Vienna. As to the former process, it here met with great approval, and will probably be adopted universally whenever applicable; and Dittel's elastic ligature is evidently of great use in many operations on fistula in ano, as has been well shown in the pages of the *MEDICAL PRESS AND CIRCULAR* by Mr. William Allingham quite recently. The method of galvano-caustic surgery, so much made use

WEDNESDAY, JANUARY 6, 1875.

FAREWELL TO 1874.

EVERY year of this wonderful century in which we exist demands a careful record in journals that occupy themselves with the physical sciences. Year by year a band of devoted workers are clearing away obscurities and overcoming some of the myriad difficulties that encompass man in his contact with external Nature, and the year 1874 has had its fair share in the triumphs of human thought and skill. How could it be otherwise? Not only in Europe, but even in Asia and Africa there are now colonies of men from the most advanced nations continually sending contributions to the vast accumulations of knowledge we now possess, bequeathed by sages of the past; and within the last fifty or sixty years there has arisen a vast nation in North America, composed of descendants of the English and German races, which is already emulating in acuteness of research and in practical energy the best efforts of the most advanced of our old countries.

Among the novelties of 1874, we may advert above all to the discussions which have followed the remarkable experiments made by Prof. Ferrier upon the brains of dogs and other animals, which have so greatly added to our knowledge of the functions of the various parts of the brain. Similar experiments had been made by Hitzig and Braun, and also by Dr. Burdon Sanderson, the latter

of in Paris of late, has been much advocated by Mr. Bryant, and the chief difficulty, that of the acquisition of a good battery, has been overcome in great measure by the adoption of carbon and bichromate of potash elements. Dr. Billroth has performed the wonderful feat of extirpating the larynx and epiglottis successfully in cases of carcinoma in two cases. Sir Wm. Fergusson has made a further addition to his reputation as a finished operator in his recent method of cutting through the hard palate in cases of cleft-palate and bringing the flaps thus easily together. Mr. Hutchinson's paper on the "Mercurial Treatment of the Early Period of Syphilis" has done much to reinstate mercury in all its ancient splendour as an antidote to syphilis at its early commencement. Thoracentesis has been largely practised both in England and in America, and the aspirator of Dieulafoy has been tried, not only in emptying the chest in empyema, but even in puncturing the bladder in cases of retention of urine. Ovariectomy continues to be practised in all countries with increasingly good results; in one operator's hands we hear of 100 operations and only ten deaths.

Discussions on cancer and pyæmia have taken place at two of our London societies—the Clinical and the Pathological; but, although a great deal of valuable evidence was given by the various eminent speakers, we must say that these very important diseases are still very mysterious, and likely to remain so for a long time to come. The speeches of Prescott Hewett and Erichsen on pyæmia will be especially remembered; and those of Paget, Simon, and Jenner in the debate on cancer. The meetings of the Royal Medical and Chirurgical Society have been decidedly dull during the year 1874. We can scarcely remember any paper of great human interest which has been brought forward. There is, we suspect, too much stateliness and pomposity in this society to allow of its being so useful to the advancement of science as the less expensive and more popular societies, such as the Medical, the Clinical, the Pathological, and the Obstetrical. Were it not for the excellent library of the Royal Medical and Chirurgical Society, indeed, we should say that it is the least useful of all our London medical societies at present. We should suggest that the Council should encourage discussion on subjects of more general interest, and not dwell in details and decencies for ever. The Medical Society of London is, perhaps, the most popular and friendly gathering of the profession in London; and, under the presidency of a most able and eminent Fellow, Mr. Victor de Méric, the Society has for the first time published an excellent little volume of its transactions. Dr. Broadbent's lectures on the "Syphilitic Diseases of the Nervous System" were delivered there with great *éclat*, and have given the profession an idea of the numerous dangers which result from the virus of syphilis when once it has effected an entrance into the system. Mr. de Méric's eloquent oration on Ricord and his School was listened to with great admiration by a numerous auditory, and elicited an animated discussion. The last meeting of the society was signalled by a very remarkable paper, written by Mr. W. F. Teevan, on the "Treatment of Stricture of the Male Urethra," which will in all probability prove a death-blow to those processes for instantaneous splitting of strictures, lately so

much in favour with a certain number of London surgeons. Mr. Teevan mentioned thirty-nine deaths as having followed from the operation which was invented by Perrève, of Paris, but long ago abandoned in his own country, which, Mr. Teevan added, stands in the first rank in all that belongs to the surgery of the male genito-urinary organs. In the Obstetrical Society of London we have not heard of much novelty during 1874. It would seem as if the Society had done so much good work for some years past that it has determined to take a rest for a year. The discussion on perchloride of iron in flooding was, however, very instructive, but rather wanting in that courtesy which is quite imperatively required by us now-a-days *inter medicos*.

The British Association and the British Medical Association had particularly interesting meetings in 1874. The speeches of Tyndall and Huxley in Belfast have raised on all sides discussions upon some of the most important questions in physiology and psychology, which no medical man can afford to be ignorant of. The remarkable essays of Mr. J. S. Mill came just in time to add new fuel to the controversy as to the limits of our knowledge, and the suppositions we may legitimately make as to other revelations concerning Nature beyond those afforded by the experience of past generations of our race. The said essays are an attempt to hold out a flag of truce which both parties—the experientialists and the intuitionists—may accept for a time. Interesting discussions took place on the effects of alcohol and tobacco at Norwich; and we can only regret the distressing occurrence of a prosecution having taken place on account of certain rather careless experiments made on poor dogs by a French *confrère*. We hope that in future all *necessary* experiments may be thought out and conducted without pain to the animal. There is now a Pharmaceutical Association, and we sincerely trust that ere long there may ensue a separation between medicine and pharmacy, similar to that which is maintained by law and custom in France, and which, we are certain, will be to the benefit of both. Dr. Lyon Playfair's address on Public Health at the Glasgow meeting of the Social Science Association showed how terribly Glasgow yet suffers from drink and over-crowding, and how much is yet to be done in Scotland to bring the death-rate to its possible limit. The Society for the Advancement of Science, held in Lille, was graced by a most important paper, by Dr. Wurtz, on "Atomic Chemistry."

The General Medical Council has done very little in 1874 for the interests of the medical profession. It has languidly listened to reports concerning education, and recommended that teaching and examining should not be in the same person, a remark which has long been a truism. Why not have a set of examiners appointed to examine all students, wherever educated? This, of course, is too *thorough*, and will not be accepted by the Medical Council, which is a weary affair in many respects to think of and to write about.

In therapeutics there was but little novelty in 1874. The value of alcohol as a remedy in various diseases bids fair to be taken up as a subject of discussion very shortly. The treatment of typhoid fever by the cold bath, so much praised by Brand, has taken the wind from the sails a

those who alleged that a bottle of brandy daily was absolutely necessary in bad cases of this disease; and the articles written by Dr. Parkes concerning rum-rations served out to our troops in the late Cape Coast war tends to prove that men who had no alcohol did better than those who took it.

A distinguished member of the profession has, during the past year, been found to advocate cremation as a means of disposal of the bodies of our friends and relatives; and as far as we may judge, there seems to be a growing desire on the part of the better-educated classes to give this plan a fair trial. Not that this is so very pressing a matter as yet.

Cholera has now entirely disappeared from Europe. Plague has been heard of in Asia and Africa, and has, in some instances, caused great ravages among the filthy and ill-drained cities of Asia.

Dr. Hardwicke has been, we are glad to see, elected Medical Coroner for Central Middlesex. Dr. James Edmunds has been elected Medical Officer of Health and Public Analyst for St. George's and St. James's districts. Mr. Erichsen has visited the United States, and has received a most fraternal welcome from our able and scientific American brethren, which has done much to draw closer the ties of mutual esteem and reverence felt for each other by all true followers of the healing art.

Cambridge and Oxford have been visited severely by outbreaks of typhoid fever, attributed, we believe, to defects in drainage. The towns of Over Darwen and Lewes have also suffered greatly. Winchester, Woolwich, and Epping have all been visited by epidemics this past year; and all these are reported as most deficient in drainage requirements. Dr. Letheby's inaugural address on the Health of Towns has created quite a sensation, and will doubtless do much to bring the subject of town and country life again before public attention.

The London Hospital Sunday is now a success. As much cannot be said for Hospital Saturday, which movement has proved too costly, and is not popular with the profession, since it is supposed that artisans and operatives in the receipt of good wages may in future, by a small subscription, consider themselves entitled to medical relief in times of sickness, and behave rudely to medical men doing onerous and unpaid services. The whole system of London medical charities is under discussion, and something like a revolution is required to make medical charity at all compatible with the interests of those medical men in London who desire to live by their profession.

The end of the year 1874 has been signalised by a period of intense cold, which has greatly raised the mortality in all of our cities. The extra mortality obtaining in cold seasons is one of the clearest proofs, if any were wanted, of the comparative backward state of modern civilisation after all. That a few cold days should be able to cut off so many thousands of the weakly among the old and young is a sign how miserably a vast number of our poorer neighbours are housed, fed, and clothed. Dr. Letheby's admirable paper distinctly shows the evils of crowding into towns, and the benefits of country life; and it is clear enough that our population is far too urban.

We have to chronicle, alas! a terrible accident on the

Great Western Railway, where a large number of unfortunate Christmas travellers have been done to death by some carelessness in railway construction. Coming after the terrible catastrophe of Norwich, such horrors may make us pause and reflect that all is not progress in this our day; but that much careful thought and prudence is required yet, before even such civilised states as the one we inhabit are free even from the most glaring and hideous evils.

ADULTERATION ITEMS.

THE legal columns of the *Pharmaceutical Journal*, in which are, from week to week, reprinted a few out of a multitude of prosecutions for trade frauds, furnish us with some instructive items of reading as the product of the seven days before Christmas.

Four grocers in different parts of the country were prosecuted for selling pickles coloured by copper and acidulated with sulphuric acid. The attorney for Messrs. Lazenby, who supplied the pickles, admitted the presence of sulphuric acid, but denied the copper, and the magistrates, who seemed very willing to get an excuse for letting off the delinquents, granted adjournments in every case, in order that an independent analyst might be referred to. At Leek, in Staffordshire, two shopkeepers were charged with selling sophisticated pepper, which was sworn to contain "husks, starches, and micaceous and ferruginous sand to an extent injurious to health." They were mulcted in 5s. each, not, we presume, for cheating the public, but for shirking their taxes, pepper being an excisable article.

Two cases, more interesting to the profession, were heard at Tunstall, where druggists were found guilty and fined 10s. each for "selling a certain drug—viz., 'precipitated sulphur,' on the 23rd November, which the analyst's certificate stated was adulterated with gypsum to the extent of 62 per cent., and injurious to invalids and children."

It will be remembered that some years ago a large firm of drug contractors to Irish unions were caught supplying this article for pauper use, but we believe that no one incurred any penalty except the too honest doctors who discovered and exposed the fraud, and were at once snubbed by the board of guardians for doing so.

A soda-water manufacturer at Glasgow was also prosecuted for selling lemonade containing lead. The medical officer of health for the city, said that his attention had been frequently directed lately to the fact that lead to a dangerous extent was held in solution in some descriptions of lemonade or soda-water. Steps had therefore been taken by the inspector of nuisances. There were authentic cases on record where one-hundredth part of a grain of lead per gallon had produced symptoms of poisoning, and one-seventy-fifth part of a grain in other cases. One-sixth of a grain was a very serious proportion. No person could partake of such an adulterated liquid without incurring very much risk. As it transpired that this offender had been previously warned, he was fined £5 5s., and costs.

ADULTERATION OF MILK.

At Greenwich, an extensive farmer was charged with selling milk adulterated with water. Special interest was excited, owing to the prosecution having three analysts in

attendance to support the certificates made in this and other cases by Mr. Heisch, the district analyst, whose accuracy, or rather whose standard of milk purity, was questioned by the prisoner, because in April last a friend had drawn a sample of milk from a cow, and handed it to Mr. Heisch, who reported it as containing at least 12 per cent. of water, whereas it was said to contain none.

On the evening of the 19th November, between six and seven o'clock, a girl was sent to the farmyard of the defendant by the inspector appointed under the Adulteration of Food Act, and obtained two pennyworth of milk from a servant to the defendant in a jug given to her by the inspector, who was in waiting, and who took the jug, and whose analysis showed an adulteration of 10 or 11 per cent. of water. The defendant had been twice previously summoned and fined on similar complaints. The correctness of the analysis being disputed, the case was adjourned. In support of Mr. Heisch's analysis, Dr. Dupré and Mr. Wigner stated that portions of the same milk analysed by them after the dispute arose (one analysis only taking place the previous day, the milk then being just a month drawn) contained as much as 12 per cent. of water. This was after making proper allowance for decomposition. Mr. Heisch said he found it to contain at least 12 or 15 per cent. of added water and to be otherwise so abnormal that he placed samples of it in the hands of the three analysts for their opinion. The analyses all agreed and quite confirmed his own. Professor Atfield said he had analysed the April milk, and found at least 12 per cent. of added water in it and three times as much common salt or chlorides as ought to have been present. A fair percentage of non-fatty solids in pure milk was 9.3, especially in the case of large dairies or herds of cows, but in order to give the milk-seller the benefit of any doubt, analysts assumed that milk placed in their hands for analysis had been yielded by the poorest cows, the minimum of whose non-fatty milk solids was 9 per cent. In reporting on the April milk he had taken 9 per cent. of non-fatty solids as a standard, a lower percentage than he had ever known to be contained in genuine milk from a herd of cows. Dr. Dupré said, in answer to Mr. Balguy, that it was admitted that there was so much difference of opinion among professional men that meetings had been held at which to fix the standard for analytical purposes, and some analysts have adopted 9.0 and others 9.3 per cent.

The magistrate thought that the circumstances of the taking and keeping of the milk were not satisfactory and dismissed the case.

Notes on Current Topics.

The Alleged Case of Poisoning by Oxalic Acid at Scarborough.

The town of Scarborough has had a great sensation lately in the supposed death by poisoning of Mrs. Margaret Pickup, an elderly woman, who died on the 28th November under rather singular circumstances. Mr. Dale, the coroner in charge of the case, and who made the post-mortem examination, considered that the vomiting, which occurred before the patient's death, was caused by her

having taken a large quantity of oxalic acid in some gin and water at night before going to bed. He found also that there were some appearances in the stomach and œsophagus which looked as if some irritant poison had been taken. There were, it seems, red patches in the lining membrane of the gullet, the stomach, and upper part of the intestines. The patient had complained of sickness and burning pain in the epigastric region. The stomach and intestines were examined by Mr. Scattergood, formerly lecturer on forensic medicine in Leeds Medical School, and he found traces—half a grain—of oxalic acid in the contents of the stomach. On this the jury, acting on the evidence of Mr. Dale, gave a verdict that "Mrs. Pickup died from poison, but how, by what means, or by whom administered, there is no evidence to show."

We should have expected the evidence to be much more explicit and clear to warrant the jury arriving at this verdict, as there seems to be no proof forthcoming that the deceased had partaken of oxalic acid, and the appearances in the stomach and gullet seem to have been ill-marked.

Taxes on Quackery.

THE introduction of a Bill into the Texan Legislature to regulate the practice of medicine in that State, has afforded, according to the *Pharmaceutical Journal*, an opportunity for the Texas Medical Society to bring forward a rather eccentric amendment. This amendment provides that any person, who is not a citizen of the State, who shall advertise therein his ability to cure disease or perform surgical operations, shall pay the same tax as is paid by persons exhibiting a circus performance or menagerie, and shall be liable to the same penalties if he commence his public performances before paying the tax.

Deaths in Cold Weather.

IN the first week of December the cold in London was very great, and the mortality rose at once and surprisingly. In the four weeks ending November 7th the mean temperature was 51°, and the deaths 5,450; whereas, in the four weeks ending December 5th, the average temperature was 39°, and the deaths 7,359, or more than 2,000 in excess. These deaths occurred chiefly in children under five and in persons over the age of forty.

Aortic Aneurism.

AT a meeting of the Royal Medical and Chirurgical Society, on the 8th ult., Dr. C. J. B. Williams in the chair, a paper was read by Dr. George Johnson on the laryngeal symptoms resulting from the pressure of aneurismal and other tumours on the vagus and recurrent nerves. The main object of the paper was to demonstrate and explain the fact that bilateral spasm and bilateral palsy of the larynx may result from the pressure of an aneurism or other tumour on the vagus nerve of one side only. In support of this, Dr. Johnson quoted two cases. In the latter, a man, aged 45, suffering from shortness of breath and stridor, was found, on laryngoscopic examination, to have bilateral palsy of the vocal cords, which, preserving their natural colour, were nearly motionless on vocalisation, and were pushed together on inspiration and apart on expiration. There was impulse and dulness over the

manubrium sterni. The patient had become hoarse eighteen months before, and had suffered much from dyspnoea, especially at night. Tracheotomy was performed the day after his entrance into hospital, but he died. After death an aneurism was found springing from the posterior part of the aortic arch, and displacing the left vagus forwards, while the left recurrent laryngeal was carried behind the tumour and nearly buried in it. Dr. Douglas Powell, Dr. Sibson, Mr. Norton, Dr. Symes Thompson, and the President took part in the debate.

Testimonials to Medical Brethren.

THE inhabitants of Wrexham are about to offer a testimonial to Mr. T. Griffith, as a reward for the energy he has shown for forty-five years in aiding the infirmary. A portrait in oil has been fixed upon to commemorate his benevolent and beneficent activity. Mr. H. A. Reeves, of the London Hospital, has been presented with a handsome post-mortem case by some of his admiring pupils for his ability, perseverance, kindness, and courtesy as a teacher in the London Hospital Medical College.

Mr. Teevan on Dilatation in Stricture.

At a meeting of the Medical Society of London, on the Monday before Christmas, Mr. Teevan read a most valuable and convincing paper on urethral stricture in the male, which he summed up by quoting the following expression of Delpech, delivered many years ago: "Dilate when you can, cut when you can't." There was an unanimous expression of opinion on the part of the Fellows present that forcible rupture of strictures was a dangerous procedure, and Mr. Teevan mentioned that no less than thirty-nine deaths directly caused by forcible dilatation had come under his notice of late years. We have seldom listened to a more convincing paper than that delivered by Mr. Teevan, and as we did so, we felt again the value of these specialities, which are, of course, so often abused in London, but which are so serviceable in solving knotty questions such as this is. It is to be regretted that neither Mr. Barnard Holt nor Mr. John D. Hill were present at the debate, since the immense experience of these two most able upholders of forcible dilatation would have proved of great service in eliciting truth. As it was the verdict was given in favour of dilatation and cutting by all who spoke.

Dysmenorrhœa.

At a recent meeting of the Obstetrical Society of London Dr. George Hoggan read a paper on "The Nature, Cause, and Treatment of Membranous Dysmenorrhœa," illustrated by microscopic specimens and diagrams. The specimen was formed of two different structures, continuous with each other; one from the vagina, consisting of the pavement-cells of the part, the other from the uterus, formed of embryonic tissue in its early stage, and identical with the structure of the decidua. This rare specimen explained the different views on the subject; one school maintaining it to be an exfoliation, the other, an exudation; the fact being that different observers had examined different ends, and therefore structures of the same membrane. From the symptoms, the membrane seemed due to inflammation. To the naked eye, and under the micro-

scope, the vaginal portion resembled such products of inflammation as the skin of a blister, or the membranous cast of the urethra thrown off in urethritis. The conclusion, therefore, was that the uterine portion, continuous and contemporaneous with it, was also due to inflammation; but, *vice versa*, the uterine portion which was identical with the decidua was probably due to the same cause, *i. e.*, excessive vital stimulation, and the vaginal portion continuous with it likewise. It was, therefore, reasoned that inflammation and excessive vital stimulation were the same, the latter being now offered as a new and correct definition of inflammation. The rational treatment, which he had employed with success, was to lower generally the generative action by anaphrodisiacs, or the bromide of potassium in large doses, prior to the commencement of the period.

The Royal Institution.

THE programme announced for the coming session at this institution, for the Friday evening meetings before Easter, 1875, is as follows:—

Professor Tyndall will lecture on "Some Acoustical Problems."

Sir John Lubbock, Bart., on "Wild Flowers and Insects."

Professor Huxley, on "Recent Work of the *Challenger* Expedition, and its Bearing on Geological Problems."

James Dewar, Esq., on the "Physiological Action of Light."

Professor Frankland, on "Climate."

W. R. S. Ralston, Esq., M.A., on "Popular Tales: their Origin and Meaning."

Professor Abel, on "Accidental Explosions;" and Dr. Liebreich, on "The Real and Ideal in Portraiture."

The following are the lecture arrangements for 1874-75.

John Hall Gladstone, Esq., Ph.D., F.R.S.—Six Christmas lectures (adapted to a juvenile auditory), on the "Voltaic Battery."

E. Ray Lankester, Esq., M.A.—Six lectures on the "Pedigree of the Animal Kingdom."

Alfred H. Garrod, Esq.—Four lectures on "Animal Locomotion: including Locomotion on Land, in the Air, and in Water."

Professor P. M. Duncan, F.R.S.—Three lectures on the "Grander Phenomena of Physical Geography."

Professor Tyndall, D.C.L., LL.D., F.R.S.—Seven lectures on "Subjects connected with Electricity."

Edward Dannreuther, Esq.—Two lectures on "Mozart and Beethoven: with Pianoforte Illustrations."

J. T. Wood, Esq.—Four lectures on the "Discovery of the Temple of Diana, and other Results of the Government Excavations at Ephesus."

Professor W. K. Clifford, M.A., F.R.S.—Four lectures on the "General Features of the History of Science."

Ship Cholera.

THE English ship *Forfarshire* has been visited, while on her voyage from Calcutta to New York, *via* Demarara, with a fearful cholera epidemic, followed by measles, among the children, and fifty-two of the coolie passengers and the engineer have died. The *Forfarshire* left Calcutta in August, bound for Demarara with 510 coolies, and a cargo of linseed. The cholera broke out the second day, the germs of the disease undoubtedly having been brought on board ship, the first person attacked being a woman. The next day other cases developed themselves, principally among the women, and they were placed in

the hospital on deck and quarantined from the other coolies, who were apparently in good health. On the third day a young man, then a boy and two children, were attacked, and the disease triumphed over all attempts to stay its fearful progress. Within ten days as many as forty coolies were suffering from cholera. Previous to this the deaths averaged one a day. The third day the mate and the apothecary were attacked, and narrowly escaped with their lives. The engineer employed on board to distil water died. In five days thirty deaths took place, and it looked at one time as if every soul on board would be attacked. The majority of the deaths were those of children, who had not the stamina of the parents. As the cholera left measles came, but the disease was not nearly so fatal as cholera, and attacked merely children, not the adults. The cholera lasted from first to last about three weeks.

Trichina in American Pork.

ACCORDING to the *Allgemeine Medicinische Centralzeitung*, Dr. Rüper has examined a number of American sugared hams sent to Germany, and finds three per cent. of them trichinous. Twenty people were sickened at Bremen by these hams.

The Maine Liquor Law.

IN answer to an inquiry from a gentleman in England regarding the working of the Maine Liquor Law, Governor Dingley writes that the effect of the law has been wholly good, and adds: "In more than three-fourths of the State the law has been well enforced, and dram-shops are unknown. In the balance of the State, comprising the large cities, the law is not so well enforced, and in Portland and Bangor I regret to say that we are almost as bad off as we should be if we had a licence law. The result of the law on the whole, united with temperance efforts, has been greatly to reduce the consumption of intoxicating liquors and lessen drunkenness in a most noteworthy degree."

Sanitary Conference at Birmingham.

WE have been requested to mention that a conference on sanitary matters will be held at the Exchange Rooms, Birmingham, on the 14th inst. Out of about 1,500 invitations sent out, no fewer than 700 have already been accepted. The gentlemen who have intimated their intention to be present hail from all parts of the country, and include mayors, members of sanitary committees, officers of health, surveyors, and other officials connected with corporations and local boards of health who are associated and practically acquainted with questions concerning the public health. Dr. Balthazar Foster is to read a paper which will refer to the comparative death-rate of the town and other large places. The prominent subject for discussion in the afternoon will be that of artisans' dwellings, on which several gentlemen have expressed a desire to speak, but inasmuch as the time is short and the gentlemen interested in the subject are numerous, a selection will have to be made, and the allotment will be determined either by priority of application or by universally-recognised claims; but, of course, in their selection of "who is to speak," the committee must be prepared for

much hostility and dissatisfaction. Dr. A. will naturally consider himself a greater authority and a better speaker than Dr. B., and *vice versa*; however, in this particular, no doubt, great judgment will be used by those who have the direction of affairs. The responses which have been given to the invitations sent out show demonstratively the intense interest the subject of sanitary reform is exciting throughout the kingdom.

The late Sir Ranald Martin's Will.

THE will and codicil, dated May 2, 1864, and Nov. 29, 1873, of Sir James Ranald Martin, M.D., F.R.S., late of No. 37 Upper Brook Street, London, who died on Nov. 27 last, were proved on the 16th ult. by Sir Wm. Fergusson, Bart., and George David Pollock, the acting executors, the personal estate being sworn under £35,000. The testator bequeaths to Henrietta Lady Buller £200 free of duty; to his wife, Dame Jane Maria Paton Martin, certain furniture, to be selected by her, and the income of the residuary estate for life; at her death he divides his property equally among his three daughters—Miss Ann Macdonald Martin, Miss Julia Errington Martin, and Miss Amy Forbes Martin—with the exception of the articles of plate presented to him by the inhabitants of Calcutta and the medical officers of the Bengal service, which, on the death of his widow, he gives to his son, Simon Nicholson Martin; and, on his decease, to his son, with the intent that they may become heirlooms in the family.

Prize Essay on Rural Sanitary Science.

DR. LORY MARSH has asked us to publish the following:

A prize of twenty-five guineas is offered for open competition for the best essay on the following subject: "The Application of Sanitary Science to Rural Districts with a view to insure the highest Condition of Health and the Prevention of Disease."

The essay to be written in English, and to bear a motto, and to be accompanied with the name and address of the author in a separate sealed envelope, bearing the same motto as the essay, which must be limited to 25,000 words. The writing to be on one side of the paper only. Hard technicalities to be avoided as much as possible.

All essays to be forwarded not later than June 30th, 1875, to Dr. Lory Marsh, 10 Adelphi Terrace, Strand, London, to whom the copyright of the successful essay shall belong.

The essayist should address himself to the powers possessed, but not exercised, by the Local Government Board, and to the effect of diversity of opinion existing amongst its advisers; also as to any new powers it is desirable to invest the Board with. He should further address himself to the applicability of the standards of pollution of effluent waters recommended by the Rivers Pollution Commissioners, and the subject of the non-pollution of rivers.

Persons interested in the subject of rural sanitary science are specially invited to assist in making known the offer of this prize.

DURING the year 1874, one hundred and thirty-five works on medicine and surgery were published in the United Kingdom, exclusive of pamphlets, showing a slight decrease on some past years.

The Dublin Corporation and Public Health.

WE have kept our readers informed each week of the action which the municipal authorities of Dublin—through their Public Health Committee—adopted with reference to the Public Health Act. It will be remembered that, having resisted in and out of Parliament the proposal to reform themselves or their system, they consistently refused to consent to any change, and endeavoured to defeat the law by excluding the medical officers of health from its execution, and by keeping up a staff of ex-policemen and other corporate *protégés* to discharge the duties which were confided by Parliament to the medical officers. In pursuance, of this policy they voted nominal salaries to the dispensary officers, and thus forced the Local Government Board into action.

At a meeting of the Committee the week before last a letter from the Local Government Board was read transmitting order under seal determining the salaries of medical officers of dispensaries, as sanitary officers, at £25 each per annum. In relation thereto it was moved by a pawnbroker, who leads the Committee—"That, notwithstanding the order of the Local Government Board now read, we adhere to our former resolution in relation to the salaries of medical officers of dispensaries, and that the opinion ordered on last Friday be taken forthwith." A division having been called for, there appeared for the resolution, 10; against the resolution, 5.

We are very grateful for the characteristic wooden-headedness which induces the Committee to oppose the Local Government Board, and we trust that, having pledged themselves—as we anticipated they would—to a policy of stupidity, the Committee will not on any account be induced to act sensibly. Probably if they had been diplomatic, and fixed even £15 a year, making at the same time some empty promises, the Local Government Board might have acquiesced, and the medical officers would have been £10 the poorer. It is easy to predict how the Public Health statutes are likely to work under the hands of such a Committee.

Irish Pharmacy.

THE approach of the Parliamentary campaign inspires the profession with anticipations as to the contemplated adjustment of the pharmacy system in Ireland. No doubt Mr. Errington will make an early move towards passing into law the recommendation of his last year's committee, that a pharmaceutical society for Ireland should be established; but it is hardly to be expected that such a proposal would receive the assent of Parliament. The conclusions which remain fixed in the minds of the profession as the result of all the talking and writing which the subject has evolved may be epitomised, although the deduction from those premises is not so evident.

It seems to be agreed on all hands—

a. That the old practitioner-druggist licence of the Dublin Apothecaries' Hall is dead, and only awaits decent cremation by Act of Parliament.

b. That under no pretext can the directors be allowed, as they propose to do, to revive their old idol by the creation of a new and superior class of druggist-apothecaries.

c. That the requirements of the public in Ireland can

only be satisfied by the establishment of a thoroughly competent class of non-medical dispensers.

d. That if this object can be achieved by the instrumentality of an efficient and permanent Irish organisation, recourse shall not be had to the English society; but that, if not, the extension of the Pharmacy Act, *pur et simple*, would probably serve the purpose.

The consideration of these premises may be aided by a recapitulation of the last year's working of the examination system of the English Pharmaceutical Society as given in its official journal last week.

"The approach of the time for enforcing the amended regulations for conducting the examinations sanctioned by the Privy Council in 1873 has been marked by what might almost be termed an examination panic. The number of persons seeking to pass the Minor examination increased at each successive meeting of the Board until it culminated in June at 343. Of course, where the passing of the qualifying examination under the least stringent conditions was so manifestly the main object, the inevitable sequence was the appearance in the examination room of an unusually large proportion of imperfectly educated men. The result is obvious. Of 1,064 Minor candidates examined under the old regulations, only 352, or 33.03 per cent., passed, against 51.95 per cent. in 1873; and on the last occasion in London the percentage of successful candidates fell below 32 per cent. The statistics of the Major examination are somewhat more satisfactory; for although the number of candidates has been somewhat smaller the proportion successful has been larger. The figures are—1873: of 83 examined, 54, or 65.06 per cent., passed; 1874: of 69 examined, 51, or 73.91 per cent., passed."

These figures at least prove that there is no intention on the part of the Society to sell its licences too cheap, or to make money by the admission of candidates whose competency is doubtful; and it definitely disposes of the objection raised by the Dublin Apothecaries' Hall that the London pharmacists would flood Irish society with half-educated apothecary-druggists.

The objection which we entertain to placing Irish pharmacy in the hands of the London society arises not at all from any want of confidence in their vigilance or incorruptibility, but because we fear that an arrangement constructed to meet the requirements of the English general practitioner system will totally fail to accommodate itself to the Irish system. We may, however, congratulate the profession and the public that no alternative which has been proposed can possibly be worse than the continuance of the farce in which the Directors of the Dublin Apothecaries' Hall have so long pretended their belief. Whatever body wrests the control of pharmacy in Ireland from the Directors, the profession and the public will undoubtedly gain by the change.

The Adulteration Law of 1874.

THE *Pharmaceutical Journal*, in its summary of the events of the past year, devotes considerable space to an epitome of the prosecutions for adulteration which it has recorded in its columns, especially those of interest to chemists and druggists, and the list completely justifies the legislation against trade frauds which Mr. John Bright considered so superfluous. Amongst the prosecutions recorded, the following present points of special interest to the chemist and druggist:—

"Conviction of a druggist for selling mustard containing

flour, on the grounds that its efficacy as a drug was thus impaired; three prosecutions for the sale of sulphur containing varying quantities of gypsum, the first being abandoned because the preparation had been sold as "milk sulphur," the others resulting in convictions, because the preparation had been sold as "precipitated sulphur;" a prosecution for selling citrate of iron and quinine adulterated with cinchonine and quinidine, dismissed because of the small proportion of alleged adulterants and their possible origin from the same source as the quinine; a conviction for selling quinine largely adulterated with sulphate of cinchonine; two convictions for the sale of scammony containing in one case only 46.01, and in the other 47.96 per cent. of resin; a prosecution for selling scammony alleged to contain 5 per cent. of flour and 3 per cent. of chalk, but admitted to contain upwards of 70 per cent. of resin, which was dismissed and led to the abandonment of other prosecutions that had been initiated; a prosecution for the sale of red precipitate alleged to contain 5 per cent. of oxide of lead, which was dismissed, but defendant ordered to pay costs; a prosecution for the sale of soda-water devoid of soda, which was dismissed, but a case was granted; a conviction for sale of lemonade containing lead; and prosecutions for the sale of preserved vegetables containing copper, and vinegar containing sulphuric acid. Amongst the curiosities of analytical prosecutions may be recorded one for selling "conversation lozenges" containing one-ten-thousandth part of powdered glass, and one-tenth of starch, and another for selling "burnt almonds" containing too large a proportion of bitter almonds. Another conviction was for selling a "liquid extract of beef," described as consisting chiefly of extract of beef, wine, a small quantity of fine old brandy and quinine, but which the analyst certified to contain but a very minute quantity of beef, no quinine, and no brandy. Early in the year Mr. Mackay, of Edinburgh, brought forward a case in which a firm of analysts certified that some Natal arrowroot taken from an original package contained from 10 to 20 per cent. of torrefied arrowroot or other starch, a statement that was flatly contradicted by four other eminent analysts to whom samples were submitted. In this case the mistake only resulted in the annoyance of having the package returned by the customer as adulterated; but in July a prosecution was commenced for selling arrowroot that was certified by a public analyst to be adulterated with another starch, which was dismissed by the Bench acting upon a certificate of Dr. Voelcker that the arrowroot was pure. Another case of adulteration that has been before a law court, though not under the Adulteration Act, was in respect to a sale of adulterated musk pods."

DIPHTHERIA has almost vanished from the soldiers' huts at Woolwich; last week there was but one death.

A TERRIBLE famine prevails in Asia Minor, with the usual results, disease and death.

THE health of the Gold Coast is reported by latest telegram to be very bad.

SINCE the publication of our last, a new king has been proclaimed for Spain. Let us hope the act will put an end to that terrible conflict which for the past two years has devastated that beautiful country.

THE death is announced, on the 6th of Dec., of Dr. Friedrich Rochleder, Professor of Chemistry in the University of Vienna. A pupil of Liebig's, Rochleder was Professor of Chemistry at Prag for many years, and at Vienna for the last. His lectures in the new laboratory of the University were much frequented by the students.

DR. MACDONALD, Professor of Natural History for the past twenty-four years in St. Andrews University, died on Friday last.

MR. HORATIO PURSLEY, of Weston-super-Mare, has presented to the authorities of the hospital of that town a cheque for the sum of £1,000.

THE Lettsomian Lectures of the Medical Society of London will be delivered by Mr. Maunder, Surgeon to the London Hospital. His subject is "The Surgery of the Arteries."

MISS ALICE VICARY, the first and only registered lady pharmacist in England, has just passed, in company with Mrs. Kingsford, the first year's examinations of the School of Medicine of the University of Paris.

A MOVEMENT is on foot for the establishment of a society for the prevention of cruelty to animals in Bombay. Perhaps there is no city in the world where repressive measures of this kind are more needed.

TWO new medical journals have made their appearance in Italy: one, "La Rivista Calabrese di Medicina Chirurgia, e Pharmacia," edited by Dr. Placido, of Reggio; the other, "La Sferza," a popular journal of hygiene and education, edited by Drs. Temistocle and Ulisse Santopadre.

A DEATH from hydrophobia occurred last week at St. Bartholomew's Hospital. The deceased, a man, aged 47, was bitten three months ago, but nothing beyond a little pain occurred until a few days since, when symptoms of hydrophobia set in, which shortly terminated in death.

AN examination of candidates for commissions in the Medical Department of the Army will be held in London on the 15th February.

Examination of candidates for admission into the Medical Service of the Navy will also take place at the University of London, Burlington Gardens, at the same date.

By the will of Mrs. Emily Woolsey, late of 49 Westbourne Terrace, London, the Hospital for Sick Children, Great Ormond Street, Bloomsbury; the Consumption Hospital, Brompton; St. Mary's Hospital, Paddington; the National Hospital for the Paralysed and Epileptic, Queen's Square, Bloomsbury; and the Royal Hospital for Incurables, Putney Heath, are entitled to £500 each.

AT the hearing of the adjourned summonses against the owners of some houses for refusing to construct proper drains at Hollin Grove, the seat of the late fever epidemic at Darwen, the Bench made an order empowering the rural sanitary authority to carry out sewage works for the houses in question, and to charge the owners with all the costs of the same.

MR. FITZGIBBON, son of Master Fitzgibbon, and formerly medical officer of the Clondalkin Dispensary, near Dublin, has been appointed Surgeon of the City of Dublin Hospi-

tal, in room of Mr. Tufnell resigned, and Mr. Tufnell has been elected Consulting Surgeon in the room of the late Professor Hargrave. The other candidates for the vacancy we believe, were Mr. Josiah Smyly and Mr. Collins. Mr. Fitzgibbon is an M B., M.S. Univ. Dub., &c.

DR. J. F. CADLE, the surgeon on board the ill-fated *Cospatrick*, was a native of Newent, near Gloucester. He had previously been two voyages to the Antipodes, and after the last intended settling in private practice, but, yielding to a pressing solicitation, he agreed to take the voyage which has proved so fatal. He was about thirty years of age, unmarried, and gave great promise of achieving a reputation in his profession.

New Inventions.

ABDOMINAL BELTS.

Two belts have been forwarded to us by Messrs. Salmon and Ody, of 292 Strand, one for males and one for females. These belts are, it seems, patented by Mr. Dixon, of Nottingham.

The female belt is made of drab satin jean, lined with red flannel. Its special feature is, that flat pieces of cork, stitched through perpendicularly, are used instead of whalebone, to lend the required stiffness. By this means the wearer has much more freedom of movement, and all risk of bruising is avoided. The idea is novel. It remains to be seen whether the cork used in this way will become as brittle as cork socks usually do after being in wear a short time.

The belt is exceedingly well made. By means of a series of elastics gathered into a lappet furnished with a button-hole, and buttons placed at intervals, it can be adapted to almost any figure. There is also a narrow band running round the lower part of the belt, which can be tightened or loosened, according to the degree of support required. Doubtless this belt will be much in favour with pregnant women, and we highly commend it for such cases.

The male belt is also admirably contrived, and will prove of service in numerous cases, particularly in the saddle.

Correspondence.

THE IRISH COLLEGE OF PHYSICIANS AND THE "DISSENT."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Referring to the letter signed by three of the "Dissentients" in your issue of the 30th ult., permit me to remark that the College of Physicians had for forty years, without any objection being raised to its use, employed the ballot in all elections, whether of Fellows or officers of the College, and that in the case of the electors of King's Professors, they were by Act of Parliament bound to select them by ballot; it is therefore no proof either of "ignorance" or "disingenuousness" to say that the College

seeks to have that "restored" which under the belief of its legality it had so long used.

Also permit me to point out that the Report on Membership is dated December, 1867, and that the "one portal" scheme was not brought forward till long after, and that therefore the Report could not have been drawn up with a view to "a change of front" in opposition to that scheme—indeed, the "one portal" idea had not been even mooted in the College at the time the Report was drawn up; the fact is, that although in 1867 the College was sensible of the desirability of instituting an Order of Members, they were deterred from seeking the power to establish it, as they found an Act of Parliament would be necessary. The introduction of a Medical Bill by the Government in 1870 merely gave them an opportunity of obtaining the power, and furnished them with fresh ground for seeking it, as your correspondents point out, but was not the cause of the determination of the College, which had been formed more than two years previously.

Since 1867 nothing has occurred to alter the case; the injustice to the Licentiates of the College remains undressed.

The foregoing facts will enable your readers to judge to whom the epithets "ignorant," "disingenuous," "deficient in candour," so freely used by your correspondents, are most applicable.

Your obedient servant,

A FELLOW OF THE COLLEGE OF PHYSICIANS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In a letter signed by Dr. Lyons, Dr. Cruise, and the Rev. Dr. Haughton, which appeared in the *MEDICAL PRESS AND CIRCULAR* of 30th Dec., the following occurs: "The proposal at that time (*i. e.* Dec., 1867) to create the order of Member was a change of front rendered necessary by the action of the British Medical Association in favour of the 'one portal' system." The foregoing statement is entirely incorrect.

At the time referred to, 1867, I was the Registrar of the College, and in consequence of the repeated representations made to me by Licentiates who felt themselves aggrieved at their inability to obtain the title of Member, I obtained the appointment of a committee to inquire into and report on the whole subject of Membership. I was present at every meeting of the Committee, and drew up the Report, which was subsequently signed by the other Members of the Committee, and can positively affirm that no allusion was ever made to the "one portal" system either at the meetings of the Committee or at the debates which subsequently took place in the College, on the presentation of the Report. Indeed, it was impossible that the "one portal" system could have influenced the Committee, seeing that it was not brought forward till the autumn of 1869, the Report of the Committee being dated Dec. 1867; the reason why the College declined to act on the recommendation of the Committee at the time being mainly that an Act of Parliament would have been necessary in order to render the Membership registerable.

I am,

Your obedient servant,

1st Jan., 1875.

LOMBE ATTHILL.

CAUSE OF GOUT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In one of my articles in your paper I have stated that gout was, simply, increased vascular action of the part, or parts, or inflammation occasioned by a continued rush of arterial blood; since then I have been considering what was

the cause of gout, and it now appears that, when the blood of those who are in the habit of drinking those wines and liquors strongly impregnated with calcareous matter becomes, as it were, completely saturated with the same, it must be deposited somewhere to relieve the system, and as the arteries of the joints are the only ones which take upon themselves the deposition of such matter, Nature very naturally directs the process, and those arteries are therefore called into action, and this action will continue despite all medical aid until the whole of it is deposited, should the joints of the hands and even the elbows be called into requisition. As soon as the blood is relieved of its presence the action will cease, as I have proved but too often from personal experience; the extremes of heat and cold—even ice—had no effect upon it, and the excruciating pain was relieved only by either morphine or laudanum. If you were to see my own two great toes, as well as my knuckles, you would see what arteries can do by way of depositing such matter. I think this is the only scientific manner of accounting for the disease.

I am, Sir, yours truly,
ALEXANDER LANE, M.D. R.N.

Douglas, Isle of Man, Dec. 23rd, 1874.

Malvern College.—The following award of Scholarships and Exhibitions has been made at this School:—House Scholarships: H. Johnson, W. Hadow, E. Johnson, and J. M. Stewart, Malvern College; J. M. Smith, the Rev. S. Middleton's, Weston-super-Mare; J. T. Lawrence, Mr. T. Horsman's, Leeds. Founder's Scholarship: E. Back, H. Thomas, H. Roden, and J. A. Hauxwell, Malvern College. Entrance Exhibitions: A. Belcher, Magdalen College School; E. Theobald, Appuldercombe School; A. Greenwell and W. Thompson, the Rev. T. Gascoyne's, Spondon House, Derby; A. T. Knight, W. Salter, and G. Trevor, private tuition.

NOTICES TO CORRESPONDENTS.

COMPLIMENTARY.—It is encouraging to receive from time to time congratulatory letters from our readers; they materially help us in our uphill warfare against shams and abuses, and show us that there are men, and these not a few, in our noble profession, who have but one motive, and that is—its honourable advancement. During the past week we have been favoured with many such letters of encouragement, and with a larger number of new subscribers than usual, the new year has dawned upon us brightly and cheerily, which prospect we hope is shared professionally by all our readers. One of the letters referred to is from an eminent member of the profession in London, from which the following is an extract:—"I have long regarded your paper as the only free, unbiased journal that we possess." We esteem this as the greatest compliment the conductors of any journal can receive, for which we thank the writer, together with our many other correspondents, who will doubtless excuse us replying to them individually.

"ACUTE TETANUS."

To the Editor of the MEDICAL PRESS AND CIRCULAR.

Sir.—It would be well if Mr. H. Gray Croly, in his paper on "Acute Tetanus," published in your last number, had furnished the composition of Dr. Feile's *anti-tetanic pill*, as it seems the only new feature of his treatment, and is most probably unknown to many of your readers, in common with myself. I think it a great pity that any point connected with the treatment of so terrible a malady should be withheld from the profession, and have no doubt it was quite unintentional on the part of Mr. Croly.

Perhaps Dr. H. McDonnell, who had been a pupil of the said Dr. Feile, would be the best authority as to the composition of the medicine in question.

I am, Sir, yours faithfully,
REDLAND, near Bristol. THOS. WEBSTER, M.R.C.S., &c.

[The ingredients of the pill were communicated to the meeting by Mr Croly, and by some inadvertence not included in the report. We give the formula now:—

PILULA ANTI-TETANICA.
℞ Aloes hepaticæ, } aa gr. xij.;
Pulv. antimoniæ, }
Opii pulverizati, gr. ij.;
Syrupi simplicis, q.s.
ut fiat pil. xij. equalis; ij. ter die sumenda.

Mr. Robert McDonnell says Mr. Feile added a small quantity of *digitalis* each pill.]

VACANCIES.

Metropolitan Asylums District. Medical Superintendent for the proposed temporary Asylum for Imbecile Children. Salary, £100 per annum, with furnished house, &c. Forms of application to be obtained of W. F. Jebb, Esq., 27 Norfolk Street, London, W.C. (See Advt.)
North Wales Counties Lunatic Asylum. Assistant Medical Officer. Salary, £100 per annum, with board and residence. Address, Mr. J. Robinson, Denbigh.
Beckett Hospital. House Surgeon. Salary, £140 per annum, with rooms, &c. Applications to be addressed to the secretary, at Barnsey Hospital for Women, Soho Square, London. Surgeon and an Assistant Physician. Honorary. Applicants must address the Secretary.
Greenwich Union. Medical Officer to the Workhouse. Salary, £300. Candidates will be required to devote their whole time to the duties. Applications to the Clerk of the Guardians.
Scarborough Union. Medical Officer. Salary, £30 per annum, with fees extra. Candidates must address the Clerk to the Guardians.

MEETINGS OF THE LONDON SOCIETIES.

WEDNESDAY, Jan. 6th.—Clinical Society, 8½ p.m. Mr. Teevan will exhibit a "Cases of Subcutaneous Urethrotomy." Dr. Farquharson, "On a Case of Hæmoptysis in a Syphilitic Patient." Mr. T. Holmes, "On a Case of Naso-pharyngeal Polypus."
THURSDAY, Jan. 7th.—Harveian Society, 8 p.m. Annual Meeting. Election of Officers. President's Address. Conversation.
FRIDAY, Jan. 8th.—Obstetrical Society, 8 p.m. Annual Meeting. Election of Officers. President's Address, Dr. Bathurst Woodman, "On the Treatment of Mammary Abscess by Rest." Dr. Madge, "On a Case of Labour complicated by Pelvic Tumour and by Convulsions." Mr. Ashburton Thompson, "On Zinc Phosphate in Cases of Amenorrhœa."
MONDAY, Jan. 11th.—Medical Society, 8 p.m. Ordinary.
TUESDAY, Jan. 12th.—Royal Medico-Chirurgical, 8½. Ordinary.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

A Manual of Hygiene and Compendium of the Laws relating to Sanitary Subjects, for the Use of Health Officers. By Charles A. Cameron, M.D. London: Baillière, Tindall, and Cox.
Chelera: How to Prevent and Resist It. By Dr. Max von Pettenkofer and Dr. T. Whiteside Hime. London: Baillière, Tindall, and Cox.
Forty Years of American Life. By T. L. Nichols, M.D. London: Longmans and Co.
Hereditry: a Psychological Study of its Causes and Consequences. From the French of Prof. M. Ribot. London: King and Co.
Inaugural Address in connection with the Chair of Clinical Medicine. By Dr. McCall Anderson. Glasgow: J. Maclehose.
Letta's Medical Diaries for 1875.
Therapeutic Means for the Relief of Pain. By J. Kent Spender, M.D. London: Macmillan and Co.
The Practitioner. Temperance Journal. The Clinic. Medico-Psychological Journal. Hardwicke's Science Gossip. The Obstetrical Journal. The Students' Journal. Monthly Microscopical Journal.

APPOINTMENTS.

BROWNE, Mr. LENNOX, Surgeon to the Royal Society of Musicians, has been appointed Aural Surgeon to the Society, vice Dr. Peter Allen, deceased.
DAKRYNE, T. E., L.R.C.P.Ed., Medical Officer for the Leek District and the Workhouse of the Leek Union, Staffordshire.
DAVY, Dr. J., Clinical Assistant at the West Riding Lunatic Asylum, Wakefield.
DUKE, D. W., L.R.C.P., an Assistant Surgeon to the Hastings Infirmary.
FORBES, D. M'D., L.R.C.P.Ed., Medical Officer for No. 1 District of the Basford Union, Nottinghamshire.
HARRIS, T. D., L.R.C.P.L., M.R.C.S.E., Hon. Surgeon to the Aberystwith and Cardiganshire General Infirmary.
M'KEOWN, W., L.R.C.P.E.J., L.F.P. & S. Glas., Medical Officer, &c., for the Dirraw Dispensary District of the Ballymoney Union, co. Antrim.
MULLIN, F., L.R.C.S.I., Superintendent Medical Officer of Health for the New Ross Urban Sanitary District.
PACKARD, J., M.R.C.S.E., Medical Officer for No. 7 District of the Blything Union, Suffolk.
RAYNER, E., M.D., Public Analyst for the Borough of Stockport.
ROSSITER, T., M.D., Sanitary Officer for the New Ross Urban Sanitary District.
SMYTH, W. J., M.D., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer for No. 7, or Shipley District of the North Bierley Union, Yorkshire.
SUTTON, F., M.R.C.S.E., Medical Officer, &c., for the Willingham District of the Gainsborough Union.
THOMAS, W. H., L.R.C.P.Ed., M.R.C.S.E., Medical Officer of Health for the Maesteg Urban Sanitary District.
TIDBURY, R., M.D., C.M., L.M., House Surgeon to the Male Lock Hospital, Dean Street, London.
WADD, T. H., M.R.C.S., an Assistant Surgeon to the Hastings Infirmary.

Deaths.

BEAMAN.—On the 31st Dec., Chas. Hulme Beaman, fourth son of the late George Beaman, M.D., of 3 Henrietta Street, London, W.C., aged 89.
BUTLER.—On the 24th Dec., at his residence, Hammersmith, James Butler, M.R.C.S., late of Seething Lane, London, and Beadonwell, Kent, aged 78.
KIERNAN.—On the 31st Dec., at his residence, 80 Manchester Street, London, W., Francis Kiernan, F.R.S., in his 75th year.
OOLE.—On the 21st Dec., Geo. Fortescue Ogle, M.B., of Monument Place, Liverpool.
O'TOOLE.—At Vernon Square King's Cross Road, London, Richard Bernard O'Toole, L.R.C.S.I., Surgeon R.N., aged 88.
THOMSON.—On the 27th Dec., Robt. Thomson, L.D.S.R.C.S.E., of Denmark Hill, S.E.

LETTERKENNY DISPENSARY.—A MEDICAL OFFICER not having been appointed to the above Dispensary on Tuesday last, as was advertised, the Committee will again meet on Friday, the 15th inst., at 12 o'clock, and Candidates are invited to renew their applications, and make an appearance on that day.
Lisliennan, Jan. 1, 1875. ROBERT RAMSAY, Hon. Sec.

SURGICAL SOCIETY OF IRELAND.—The THIRD MEETING of the SOCIETY will take place on FRIDAY EVENING, 8th JANUARY, 1875.
Chair will be taken at half-past Eight o'clock precisely.
B. WILKS RICHARDSON, F.R.C.S.I., } Hon. Secs.
HUMPHREY MINCHIN, F.R.C.S.I., }
Royal College of Surgeons, Dublin,
25th day of Nov., 1874.

METROPOLITAN ASYLUM DISTRICT.—The Managers require the services of a MEDICAL SUPERINTENDENT for their proposed temporary ASYLUM for IMBECILE CHILDREN, which will contain about 450 patients. Salary £400 per annum with a furnished house, coals, and gas. Candidates, who must not exceed 45 years of age, must possess the double qualification required by the Regulations of the Local Government Board. The gentleman appointed will be required to do his own dispensing and to provide a Substitute at his own expense whenever absent from the Asylum for more than three consecutive hours. Forms of application may be obtained at the Office, 37 Norfolk Street, Strand, where applications, accompanied by testimonials, must be delivered by or before 12 o'clock on Wednesday, the 13th January.

By order,
1st January, 1875. W. F. JEBB, Clerk to the Managers.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—FIRST or PRIMARY PROFESSIONAL EXAMINATION for the LICENCE.—The next Examination will commence on MONDAY, FEBRUARY 1. Students are admitted to this Examination after the termination of the Second Winter Session of Professional Study at a recognised Medical School.

SECOND or PASS EXAMINATION for the LICENCE.—The next Examination will commence on MONDAY, FEBRUARY 8. Gentlemen who have completed four years of Professional Study according to the College Regulations, are eligible for admission to this Examination.

Registered Medical Practitioners qualified before January, 1861, are admitted to Examination under special Bye-laws.

Candidates are required to give fourteen days' notice in writing to the Registrar of the College, with whom all Certificates and Testimonials required by the Bye-laws are to be left at the same time.

Full Hall East. H. A. PITMAN, M.D., Registrar.

MALVERN COLLEGE.

This COLLEGE contains TWO DEPARTMENTS—the CLASSICAL and the MODERN. There is also a Preparatory LOWER SCHOOL.

There are Boarding Houses within the College Grounds, held by the Head Master and others of his Staff; a Gymnasium, &c.

Board and Tuition under 14, £80; over 14, £90. Non-shareholders pay an extra fee of £6. Special advantages for Sons of Clergymen and Home Boarders.

For further information apply to the Rev. ARTHUR FABER, M.A., Head Master, late Fellow and Tutor of New College, Oxford.

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

PATRON:—H.R.H. THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £35 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote.

Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c. can be had at the office.

40 MOLESWORTH STREET, DUBLIN.
W. O'NEILL, Secretary.

The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements, from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

Established 1848.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S., &c. (KING'S COLL.), and Author of VIA MEDICA.

Has always upon his books a large number of desirable Investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

PRACTICES AND PARTNERSHIPS NOW OPEN for Negotiation (in addition to those advertised in Dr. Langley's List, which is sent post free on application).

Z 82. **DEATH VACANCY.** The SUCCESSION to a GOOD FAMILY PRACTICE in a pleasant Southern County, and within 60 miles of London, can be secured to a doubly qualified gentleman accustomed to good society. The Practice has been actively carried on up to within a few days of the decease, and a reliable "Locum Tenens" is in charge. The receipts are estimated to have been upwards of £700 a year, and the books are open to full investigation. Valuable public appointments are connected with the practice. No proposal for payment out of receipt will be entertained.

Z 83. **PRACTICE or PARTNERSHIP.**—The SUCCESSION to a FIRST-CLASS PRACTICE in a good market town within easy access of London can be secured by an effective introduction by Partnership or otherwise. Receipts upwards of £1000 a year. Midwifery fees £1 ls. to £10 10s. The house contains ten rooms, with detached offices, garden, conservatory, stabling, &c. The premium required will depend upon the length of introduction agreed upon.

Z 81. Within 15 miles of London, a JUNIOR PARTNERSHIP in a good GENERAL PRACTICE, in a suburban locality. A fourth share for disposal, with succession to further share hereafter upon equitable terms. The receipts are £1,350 a year, and there is great scope for increase. There is little dispensing. The Junior could at first reside at the branch surgery. Premium, £675, part of which may be left on security, and paid by instalments.

Z 78. First-class LONDON PRESCRIBING PRACTICE, held by the Incumbent for many years. A Partnership introduction would be given, but the connection could not be transferred to any gentleman not highly qualified nor unless he were accustomed to the best society. The income averages about £4,500 a year. Midwifery fees from 7 to 10 guineas. The residence is well situate near the most fashionable west-end squares.

Z 80. In a prosperous and picturesque district, an OLD-ESTABLISHED PRACTICE, yielding in actual receipts £1,100 a year. Age the cause of retirement. Appointments bring in £62 a year. The house is well situate, contains 10 rooms, with detached surgery, offices, stabling, and large garden. Rent 40 guineas. The working expenses amount in all to about £300 a year. An effective introduction by quasi partnership or otherwise as long as may be desired. Part of the premium may be paid by instalments. The whole connection is safely transferable to a suitable gentleman, and there is great scope for increase, as there is a population of about 15,000 inhabitants.

DR. LANGLEY'S LIST of SELECTED PARTNERSHIPS and PRACTICES for disposal, for January, is now ready. Post free on application.

ON AN EPIDEMIC OF CONTAGIOUS SORE-THROAT (PASSING INTO SCARLET FEVER)

WHICH OCCURRED IN THE CRIPPLES' HOME, AND THE PROBABLE CAUSES OF ITS PRODUCTION.

By C. H. F. ROUTH, M.D., M.R.C.P.,

Physician to the Home; Senior Physician to the Samaritan Hospital for Women and Children; Consulting Physician for Diseases of Women to the North London Hospital.

THE remarkable papers of Dr. Farquharson on "Infectious Tonsillitis," and of Dr. Pearson, on "An Epidemic of Sore-throat, with marked Constitutional Symptoms," read during last session, called special attention to phases in the character of cynanche not usually observable in this disease. The following paper is a contribution in the same direction, but over a much more localised sphere, and where necessarily the etiology of the disease was more easily traceable. Dr. Farquharson did not (so far as I can judge from the abstract given of his paper) enter into the question of the etiology of the disease described. Dr. Pearson referred the cause to malaria in general terms. The chief interest of this communication lies probably in the fact that bad water here, as in cases of typhoid fever, was possibly the *foetus et origo* of the disease; and secondly, in the fact that the sore-throat assumed three different leading forms, which are usually believed to originate from distinct blood poisons.

A short account of the institution appears to me, however, to be a proper introduction to the subject. All diseases require a fit nidus for development, and it appears impossible to estimate the progress or arrest of any epidemic in this nidus, unless we have an idea of the nidus itself.

But, then, as regards the sanitary appliances at the institution, even at the risk of egotism, I am disposed to believe

they are as complete as in any other institution with which I am acquainted. Primarily as to ventilation.

In every room on a level with the ceiling are openings which are only closed by perforated zinc, not, indeed, of that variety where the apertures are so small that they are rapidly choked by dust and smut, and so soon cease to be perforations at all, but apertures about a line in diameter, and, therefore, remaining pervious continually. Nor are these openings small, but vary from two to three feet in diameter one way, by six inches to a foot in the other, and sometimes several of these are placed in the room, if it be a large one. In the dormitories the windows, which are first pulled down to admit of the insertion of perforated zinc plates, varying from 3 to 6 inches, are secured in this position by padlocks, so that the window can no longer be pulled up or down. In this manner there is a free passage of the external air at all times into the rooms. These openings, however, are not confined to the window-side of the room. Similar openings, also guarded by perforated zinc, are placed opposite to them, which open on the large central staircase, which acts as a sort of shaft for the reception of the foul air. This same arrangement of opposed ventilating openings is carried out in the basement, where several of the doors have the panels taken out, and fitted also with perforated zinc, so as to admit pure air to the bottom of the house, while at the top of the house, at the end of the large staircase before referred to, three large doors have been placed to give free exit to any air which may be impure, and has travelled there from the inhabited rooms. In this passage indeed there is invariably a strong upward current of air. It is remarkable how soon the slightest bad smell passes out this way.

Great care has also been taken with the water-closets. All communicate with the external air, and this air is admitted from the external atmosphere through large channels which come into the closet on a level with the ground, and is carried away superiorly by long shafts, so that here also there is a constant upward draught to remove all bad odours.

The means to secure a good quality of water were until lately excellent. All water drunk by the inmates was

received into a large funnel, kept constantly full by a ball and tap, in connection with the water service, and the water was made to filter through seven or eight layers (each layer of about one inch thick) of silver sand and animal charcoal. Both these latter agents were made red-hot before used, or at least put into crucibles to be purified of any retained impure vegetable or animal matters. Indeed, the sand was boiled in two or three quantities of boiling water before calcined. The water then was made to fall from a height into a reservoir, was thus excellently well filtered and aerated, and to the taste unexceptional.

Exception might, perhaps, be taken to the girls themselves. Seventy-three of these are cripples of every kind, hunchback, paraplegic, with diseased lower extremities, intensely scrofulous of temperament, weakly, many of them the children of diseased or depraved parents, and having been much neglected in infancy. The remaining girls which make up the complement of 100 are so-called refuge girls, not cripples, but occupied in the domestic work of the institution, and to assist the cripples.

With such an assemblage we need to look for much disease. The mortality is, however, remarkably small. For the most part they are under 20, but a few older girls are kept as monitors. But they are well-fed and well-clothed, and the utmost regard is paid to their comfort and regular habits.

The strictest cleanliness is observed in the Home, not only in the rooms, but as there is a large laundry and large bath-room, to the cleanliness of the garments of the girls, and of the girls themselves. The latter are obliged by the rules of the house to be thoroughly washed in a warm bath at least twice a week, and as all this is done under the personal supervision of experienced matrons all source of impurity from want of cleanliness is removed.

The arrangements adopted in cases of infection are also complete. The entire floor of the upper part of one of the houses comprising the Home has been constituted into sick-rooms, with bath and water-closet in an adjacent room in free contact with external air. It is in the passage immediately without this that the two large doors before referred to forming the summit of the stair-shaft out of which the impurities of the rooms are conveyed are placed, but in the sick-rooms themselves not only are the ventilators placed opposite to one another at the windows, but, as the ceilings here, which are about twelve feet at their highest point, are slanting in direction, ventilators are placed superiorly on the roof in addition. Lastly, in case of emergency, the dormitory beneath can be adapted for hospital purposes, being equally well ventilated. Again, whenever there is a contagious case, the doors are guarded by sheets dipped in a solution of carbolic acid, kept constantly wet, and all water used for purposes of ablution mixed either with carbolic acid or Condy's fluid. A separate nurse is provided, and all intercourse with the other inmates rigorously prevented. As the cases get well, they are compelled to take baths, and to be thoroughly washed over with carbolic acid soap and water. All their old garments are washed, and then fumigated in sulphur, before allowed to be worn again, for twenty-four hours in the sulphur steam bleaching room.

The worse cases were sent, during my temporary absence, to the Fever Hospital.

The visits of friends to public institutions are often necessary evils, and in those where, perhaps, the surroundings of the inmates' parents or friends are neither the most cleanly nor refined their visits often do harm. A middle course has, then, been adopted, and friends are only allowed to visit the inmates, except in cases of disease, once a quarter; but very rarely, if ever, are they allowed to visit their friends. However, they go out regularly, and once a year the greater number are sent for change to the sea-side.

The result of these measures has upon the whole been very satisfactory. Up to this year cases of fever and small-pox have occasionally appeared, but never spread, and when deaths have occurred, and these have been very few

and far between, the fatal disease has generally been bronchitis, to which cripples, as a rule, and especially the hunchbacks, are peculiarly obnoxious.

The following gives particulars of the epidemic in its origin and progress in a tabular form:—

FROM OCTOBER, 1873, TO OCTOBER, 1874.

It will be seen by reference to the table above given that about October, 1873, the state of the Home gave evidence of some malarious influence. The last

batch of inmates had returned from the sea-side, and one of these, who came home ill in the early part of October from the sea-side, soon sickened with typhoid fever. She was removed to Middlesex Hospital, where she died on the 26th October, 1873. No other case, however, occurred at the Home.

In the meanwhile, a new matron was introduced in the place of one who had left, and she soon afterwards had a severe attack of low fever, with very acute sore-throat, which lasted several days. On October 14th, 1873, another case among the girls occurred, and from this time till October, 1874, last month, when the epidemic appeared at least for a time to cease, forty cases more were treated, all of which recovered. But during that period two other diseases made their appearance—measles, of which there were ten cases, and erysipelas, of which there were six cases.

The epidemic of measles was mild, and gave little anxiety. It was believed that its origin could be easily accounted for. The disease had broken out with some virulence in a neighbouring school, and the inmates of this school were in the habit of occupying of a morning the pew sittings in a church which the cripple girls occupied in the evening. These sittings being placed in the upper gallery of a very ill-ventilated church, and it was believed the infection was retained in this *locale*, and so communicated to the cripples.

Of the erysipelas cases, one occurred twice in the same patient, once in October, 1873, when the sore-throat epidemic began, and again in January; but this girl had a natural disposition to this malady, which had several times before attacked her, and therefore it did not at that time lead to much alarm or inquiry. Of the three next seizures of erysipelas in other girls, only one occurred while the sore-throat epidemic was *not* prevailing; the other two occurred synchronously with the sore-throat outbreak, and the remaining three occurred when the sore-throat epidemic was apparently subsiding. One of these erysipelas cases was very ill. The disease seemed to fix its malignity on the palpebræ, both of which swelled tremendously, and a large quantity of matter formed, which, however, on being liberated, had no further bad consequences. The erysipelas was in all cases except one confined to the face and head. In this one it was confined to the thigh, and also terminated in diffuse abscess; but the girl had a scrofulous wound there.

The first three cases of sore-throat observed were slight, and apparently simple cases; two occurred in Oct., 1873, one in August, 1873, two in March, one in April. But it was in May that the virulence of the epidemic showed itself. One little girl, a weakly cripple, æt. 13, was taken suddenly ill. She did not complain exactly of sore throat, but of chest pains; but intense sickness supervened, and she died the same night. No post-mortem was allowed, and I am still at a loss to know the cause of death—whether it was due to suppressed scarlet fever, or whether it was simply a case of death from exhausted vital powers. The body rapidly decomposed and discoloured. At the same time a girl who had some slight sore-throat symptoms, and which had disappeared rapidly, two months back sickened, and this time with severe symptoms. The throat was not only very sore, and the tonsils and neck-glands much swollen, but the mucous membrane had a sloughy appearance, and here and there distinct diphtheritic threads. With this there was great exhaustion, and we once or twice thought she would have slipped through our fingers as the other had. She continued ill for six weeks, and the whole character of her attack was one of marked adynamic type. Seventeen cases sickened from this time up to the end of June, 1874. Some of these were very slight, others severe, lasting ten days to a fortnight.

Speaking generically, I may say three types were observed:—

1. Simple cases, which might in different company have been regarded as simple cases of tonsillitis, with more or less fever.

2. More severe cases, in which the throat was unusually red and inflamed, the tonsils considerably enlarged; the fever and temperature very high, with delirium; frequently sickness, followed by unusual depression and exhaustion. In some of these cases something like roseola had been observed in parts of the body, lasting for three or four hours, and then disappearing—for I may say eruptions were carefully looked for; but it was an eruption in patches about the size of the palm of the hand, and which ran no regular course, and certainly, if the patients had not been carefully watched, they would have escaped observation.

3. The distinctly diphtheritic sore-throat, characterised by great bodily exhaustion from the first. These cases formed the minority. In these the same red roseolar patches on the skin were noticed, but equally notable in character, as were observed in the former; but in none of these was a distinct scarlet fever rash, or strawberry tongue observed. In two cases petechiæ of a violet colour made their appearance towards the end of the seizure.

It was not to be doubted that the continued recurrence of these cases, and their occasional severity, should have given rise to much anxiety.

I caused inquiries to be made as to the probable cause of this epidemic, but I found nothing satisfactory to account for it. All the measures usually observed for ventilation and purification from noxious odours were more scrupulously adopted. Complete isolation was enforced, and by the end of June, as before stated, the epidemic seemed to have terminated.

But it was not so. In the month of September, extending to the middle of October, another epidemic of sore-throat broke out, and this time marked cases of scarlet fever were among the number. It was during my absence from town, when Mr. Cheyne, of Nottingham Place, kindly undertook the medical charge of the Home. His letter bearing upon this outbreak I shall read later; but I find from inquiries made, and which he kindly replied to with full particulars, that he seems to have had also three forms: Simple mild cases of what might be called common cases of tonsillitis; these he regarded as non-contagious, and after a few days they were allowed to resume their ordinary avocations, no bad results following; 2nd. Cases where the throat symptoms were much more marked, and the throat and tongue assumed that peculiar red or strawberry appearance noticed in cases of scarlatina faucium; and 3rd. Unmistakable cases of scarlet fever, with the characteristic eruption on the skin as well as the sore-throat. These two last classes were sent to the Fever Hospital, to the number of eight, and all recovered. On this point Mr. Cheyne writes:—

“Fourteen cases of sore-throat at the Cripples' Home occurring in little more than a fortnight, suggested an inquiry into the nature and cause of the outbreak, with the following results: Between Sept. 9 and 12, 1 cripple and 3 domestics were attacked with scarlet fever; and between Sept. 11 and 25, 5 cripples and 5 domestics suffered from inflammatory sore-throat. Prompt and thorough isolation was adopted in every case, and the four cases of scarlatina were sent away to the London Fever Hospital as soon as possible, the early removal of contagious cases being deemed the only effectual method of preventing an epidemic. The cases considered non-contagious recovered in a few days and returned to their usual avocation with no bad result.

“In considering the cause of the illnesses, there is no clue as to contagion; but it is believed that sufficient sources of infection have been found in the building to account for all. In the first place, it was found that the waste-pipes of the drinking-water cisterns communicated directly (*i. e.* untrapped) with soil pipes, and the smell on opening one of the cisterns was very offensive. The water, owing to an imperfect filter, had been noticed recently to be disagreeable both in taste and smell.

“A further examination of the drains disclosed some faulty traps, and this was particularly the case of a pipe from a sink near the dormitories. It was also noticed that rain-

water pipes with faulty joints were used as soil-pipes both inside and out of the house. There was also a very bad smell in the garden area, probably from unemptied closets there. To improve matters as much as possible, it was directed that all the cistern waste-pipes should be at once cut off from drains, so as to discharge in the open air. The filter has also been cleaned out, and the wood charcoal replaced by proper animal charcoal. The constant supply of water has also been stopped by the removal of the ball, so that the charcoal may be exposed to the air at least once a day to facilitate its oxidising properties.

"While it is hoped that these slight alterations may be of benefit to the institution, it is strongly advised that all drains and traps should be carefully looked to by some competent authority.

(Signed) W. A. CHEYNE."

From this masterly and succinct report, it is clear Mr. Cheyne believed that the bad water drunk and the imperfect drainage had been productive of the disease—in other words, that scarlet fever and severe tonsillitis may be produced by water contaminated with, or by the effluvia of, volatile sewage matter, as well as typhoid fever.

I confess I was surprised, after all the care I had taken to supply the Home with good water, that the reverse had been the result, and on inquiry I learned that the change in the character of the filter had been carried out by some master-workman, acting under the direction of some new officials. Being directed to clean it, he had substituted a few solid lumps of vegetable charcoal for the freshly prepared animal charcoal-powder and calcined silver-sand. This was done entirely upon his own responsibility, and kept secret, of course, from other officials, and from me in particular.

The peculiar disagreeable flavour and smell of the water was only observed during the months of August and September. This is the period when, perhaps, decomposition is most rapid, at least in London, and no doubt it was only more evident now, but perhaps had existed many months previously; but here a remarkable coincidence was observed. Only one of the monitors (*i. e.*, girls who are placed in authority over the others) suffered from the epidemic, and she was a water-drinker. The other five were allowed beer, in one case wine, and therefore did not partake of the water, except when boiled to make tea and coffee. Five of the matrons (of which there are also six) escaped in the same way, but this sixth one was a total abstainer, and therefore a water-drinker, and she was the first seized, soon after her appointment, and it was said, as before remarked, that she had brought the disease in the Home. Whether this was true or not, there is a remarkable coincidence to be observed between the water-drinkers and the cases obnoxious to the epidemic.

The periodical odour in the yard was an old grievance. Unfortunately for the managers of the institution, it is too true that mischief is not excluded from the Home, and the girls are sometimes very neglectful; and I have frequently been obliged to have the yard drains taken up to remove large pieces of house-flannel and dust-cloths, which of course fell into the drains by accident, or in some unaccountable way. But no epidemic had ever before resulted from this source, although it cannot be denied that it must have had an influence for evil.

In tracing other sources of infection, we must not omit the visits of friends and the sea-side trips.

Visitors are not admitted weekly in this Home. Once every six weeks they are allowed to come; but only half the girls at the Home see their friends then, so that the concourse of strangers from without and the inmates is very rare compared to what it is at other institutions. Of the girls who caught the first sickened 13 days, the second 14 days, the third 15 days, the fourth 16 days, and then there was a lull of new cases for 18 days, when a fifth case occurred, and next day a sixth case. Five days after two other girls were affected; but sore-throat cases, 16 in number, occurred during the same period, manifestly influenced by the same cause.

On inquiry being made among the friends, we could not hear of any cases of scarlet fever amongst them. But I am afraid to trust such statements too implicitly, because I quite feel where the knowledge of such cases existing would be made an obstacle to friends seeing them, not much dependence could be placed on their veracity.

Then, as to the importation of the infection from the sea-side. I am not aware of anything special, either at Lowestoft or Great Yarmouth, the two places visited at the beginning or end of the epidemic. Lodged in very fair and well-ventilated houses, we did not learn of the previous infection of these places, though full inquiry is always made. Still, where it is in the interest of lessors to keep such a contingency secret, there is always room for deceit.

The questions I would venture to suggest for discussion are—

1st. Are we justified in concluding that the ordinary cynanche, diphtheritic sore-throat, and scarlatina were one and the same disease, *i. e.*, produced by the same poisonous miasm, only modified by the state of the patient? It is commonly believed that scarlet fever and scarlatina faucium are the same disease, but variola and varicella are not; nor are diarrhoea and Asiatic cholera; yet the class of diseases here mentioned in pairs together do prevail conjointly, and seem to be produced by the same cause. Moreover, some of the girls who had simple cynanche had second attacks, sometimes of cynanche again, others of diphtheritic sore-throat and scarlet fever.

2nd. Was there any similarity in the miasm which produced the erysipelas? We do know both scarlet fever and erysipelas infection will produce the same puerperal fever in lying-in women. It is noteworthy that the sore-throat epidemic was noticed in two synchronously with erysipelas cases, *i. e.*, in October, 1873, and May, 1874, and temporarily ceased synchronously with erysipelas cases also in June and October, 1874.

3rd. Can the water contamination, on the evidence given, justify the belief that, like typhoid fever, sore-throat, diphtheria, and scarlet fever can be produced by sewage impregnation?

Lastly. Had the typhoid fever epidemic, then so prevalent in London, any influence in developing the epidemic. The disease was so rife at one time that the medical officer of health sent to make enquiries, it is believed, in every institution, to look for typhoid fever cases, and there are those who believe the contagious sore-throat and typhoid fever are intimately related. Only lately the opening of a drain in York Street, I am informed, has developed several of these cases, in which sore-throat and typhoid fever were conjoined.

ON A CASE OF EXCISION OF THE KNEE FOR BONY ANKYLOSIS WITH DEFORMITY (a)

By WILLIAM THOMSON, M.D., F.R.C.S.I.,
Surgeon to the Richmond Hospital.

THE case to which for a very few minutes I wish to direct the attention of the Society is one rare enough to make it of more than ordinary interest in a surgical as well as a pathological sense. The operation of excision of the knee has asserted its position in practice so strongly that it has long since lost its novelty. If it now forms subject for controversy it is in relation to the alternative of amputation, to the comparative mortality which attends it, to the actual benefit which it confers upon the subject of it; but that it is in a large number of cases a justifiable proceeding is, I think, a proposition which is now accepted by nearly all operating surgeons. It is not so, however, in cases of simple deformity, where all active disease has

(a) Read before the Surgical Society of Ireland, December 11th, 1874. The discussion will be found in the proceedings of the Society at page 30.

ceased, and the individual only complains of the clumsy attitude of the limb, and wishes relief from it. To subject an otherwise healthy person to the risks attendant upon excision of the knee-joint is a proceeding of so much gravity that one cannot be surprised that it has been seldom attempted, and that it has been by some fiercely opposed. A group of twenty cases in which it was performed gives but a gloomy result: eight patients died; amputation followed in two instances; so that the failures amounted to 50 per cent. The statistics, however, which I have been able to consult are not sufficiently definite to justify an accurate conclusion as to the actual mortality; thus, many of the cases were no doubt very dissimilar as to the actual condition of the subjects. In some, deformity may have been but a complication of existing disease in the joint, coming at the close of a period during which the patient had been undergoing gradual exhaustion. The removal of diseased structures and of an awkward distortion may have been effected by the one procedure, while fatal cases of this class have not unlikely been included in the category of operations for correction of deformity only. What we want is, statistics of the operation in cases in which the original disease has actually been recovered from, and in which the surgeon has interfered with the single object of correcting the acquired angularity. It is obvious that only from such facts can we arrive at a proper estimate of the propriety of the operation at all.

Judging from the success which has attended excision of the knee-joint in its various stages of disease, the removal of a portion of bone from an ankylosed knee would seem *prima facie* to be a most hopeful proceeding; yet Cooper and Cloquet are represented as declaring it to be unjustifiable; but it seems to me that the condition of a person so afflicted is sufficiently miserable to make its relief a most fitting object of surgical skill. Of course there are cases in which the flexion is slight enough to enable the patient to compensate for it by apparatus specially devised for the purpose; but in the more exaggerated instances he is doomed to move about with a crutch, on a wooden stump, the leg meanwhile sticking out behind and being a constant source of inconvenience and annoyance.

Amputation would be at once a radical and unsatisfactory solution of the difficulty. With risks admittedly about equal to those of excision, it would bind the patient to the constant use of an artificial limb, a condition which I think no one will claim to be comparable to the results attained in most excision cases.

We owe it to our American brethren to say that their boldness and ingenuity have contributed most to the surgery of this affection. The names of Barton, Buck, Brainard, and Gross are all identified with methods of correcting this deformity. Rhea Barton, of Philadelphia, was I believe, the first to suggest resection as the proper treatment in true bony ankylosis of the knee. His plan was to make a triangular flap immediately above the condyles, the apex being internal, and the base measuring two and a-half inches external. All the soft tissues were divided down to the bone. A wedge-shaped piece was then removed from the shaft of the femur, but not including its whole thickness. The remaining slight band of bone was broken through by increasing the flexion, and the limb straightened. Buck, of New York, modified the operation by removing the wedge from the front of the joint. Brainard, of Chicago, suggested the subcutaneous drilling of the ankylosed joint, and the operation was afterwards successfully performed by Gross. An incision half an inch long was made over the internal condyle, and a drill passed through the mass. It was then partly withdrawn, and passed in another direction, until the parts were completely honeycombed. The remaining connections were broken up, the limb was placed upon a double inclined plane and gradually straightened.

The patient whose case forms the subject of these notes was admitted to the Richmond Hospital on the 8th of January, 1874. She was a healthy-looking country girl, of good muscular development, *æt.* 21. She did not present any traces of recent illness. Her history was that

six months previously she got a severe wetting. In a day or two afterwards she was seized with pain in the left knee, which swelled considerably. She was compelled to go to bed, and had severe rigors, feeling, to use her own words, as if buckets of cold water were being thrown over her. The pain was intense and persistent, and from the first week she was troubled with violent startings in the knee as she was about to fall asleep. She did not seek any surgical or medical aid. No stupes or poultices or any of the ordinary domestic remedies were applied. She simply lay in bed with the knee flexed, as being the most easy position, and remained thus until the acute symptoms had subsided. In four months the startings began to diminish, and they soon ceased. At the end of five months she left her bed, and she then found that the joint was firmly fixed in the bent position. In a month afterwards she came to hospital in the hope of having some remedial measures adopted.

Her general aspect and condition, then, I have described. The knee did not present externally any appearance whatever of recent severe disease. The integuments were normal in colour, and perfectly healthy. There was no thickening, no effusion, no sinus. The limb was, however, bent, almost at right angles, and the girl was obliged to move about with a crutch. Closer examination revealed that the deformity did not depend upon muscular contraction, or the presence of fibrous bands. By no amount of reasonable force could the hamstring tendons be made tense. The joint was perfectly rigid. The patella was firmly adherent to the femur at the outer side, and there was some displacement of the tibia in the same direction.

The case seemed a favourable one for operative interference. The patient was healthy, there was no history of delicacy in her family, and there was good proof of her constitutional powers in her general appearance after having undergone so serious an illness. With the concurrence of my colleagues, operation was proposed to her. I made her aware of the risks attendant upon it, and having given her some days to consider, she said she would consent to anything short of the loss of the limb itself.

The operation was performed on the 21st January. I adopted Esmarch's method of bloodless surgery, with the most satisfactory results. It seems to be specially adapted to cases of excision and of necrosis, for the parts which you wish particularly to see are free from blood. The excision was U-shaped. When the flap was raised not a drop of blood escaped, the knife being only soiled by the fat through which it had passed. The patella was first removed; then a wedge-shaped piece of bone. The whole thickness of the ankylosed mass was cut out and the thin connecting-band, which remained posteriorly, was broken through by increasing the flexion. It was found necessary to take away some additional slices, and the limb was then placed upon a simple back splint, extending from the buttocks down, with a fixed foot-piece. At this point the elastic tubing was removed from over the femoral artery. Some slight oozing naturally followed, but it was not found necessary to secure any vessel. After waiting for some time, the anterior edges of the wound were brought together with pins and twisted sutures. A firm plaster of Paris casing was then applied, care being taken to prevent tilting forwards of the femur by placing a short splint anteriorly. The wound, which was of course not included in the bandage, was then dressed with some slips of lint dipped in carbolic oil, and the patient was removed to bed. There was no shock from the operation. There was slight oozing from the wound, but it soon ceased. She passed a restless night, being kept awake by vomiting, which I attributed to a morphia draught, and next morning she had frequent chills, which ended at mid-day in profuse sweating. On the second day after the operation the temperature, which had risen to 102.8° on the evening of it, fell to 99°. From that time the temperature decreased slowly. She was without pain, in good spirits, and always slept without any draught.

The dressings were first removed on the 25th, when the

whole of the wound, where the edges had been brought together, was found to have united. The sutures were allowed to remain in for ten days, as they were not causing any irritation whatever.

On the 24th of February, the plaster was removed, as some discharge had got down under the limb, and caused slight excoriation. The parts were then well cleansed, and a McIntyre's splint was applied in the straight position. In the early part of April I substituted a very light scored splint, and, finally, on the 27th of April, I put the limb up in dextrine bandage. There was then sound and strong union of the bones. The patient could move her leg from side to side, and with a little assistance raise it. The wound had closed throughout its entire extent.

On the 29th (being the fourteenth week from the operation) the patient was enabled to sit up. Her subsequent progress was retarded by the formation of a small abscess, which, on being opened, was found to be caused by a small fragment of the femur, about the size of a pea, which bore upon it the marks of the saw, and which had probably been chipped off at the operation, and allowed to remain in the wound. After this, nothing occurred to interfere with the progress of her convalescence, and she was enabled to move about on crutches early in July. She was then able to stand on the leg, to make her bed, and to get into it without any assistance. She left the hospital on the 31st August, about six months after admission, quite well. The shortening of the limb amounted to about two inches, or a little less; but with a high-soled boot she was able to go about with ease by the aid of one crutch. I have since heard of her as enjoying excellent health, and having a useful leg.

The portions of bone removed which I beg to submit form, you will perceive, a wedge-shaped block, and include the whole of the condyles of the femur, and a very thin slice of the tibia. It was found necessary to remove so much of the femur in order to bring the extremity into proper position. The patella is firmly ankylosed to the outer and lower part of the external condyle and the displacement of the tibia from the direct line is manifest. On that portion of the internal condyle, which is not in contact with the tibia some of the articular cartilage remains, but nowhere else is there a trace of this structure. The semilunar cartilages have altogether disappeared. When the flap was raised there was no sign of a synovial membrane. There was not a particle of broken-down structure, nor was there anything to show that suppuration had gone on. The bones are perfectly healthy.

The case seems to me worthy of bringing under the notice of the Society for various reasons, which I can do little more than enumerate. Operative interference of so serious a character for simple deformity of the knee-joint has been very rarely indeed attempted in this city or country. I am aware only of two such cases, one of them, I believe, having been under the care of Mr. Croly. I am fully alive to the weight to be attached to the hostile judgment of the eminent surgeons whom I have named, founded as it is upon very special experience and powers of observation; but I think the results attained in recent years must modify that judgment considerably. That the operation is one attended with much danger, no one will deny; yet it appears to me that the benefits likely to be conferred upon the patient are too great to be withheld because of the dread of possible misfortune. There are, however, conditions which are essential to the very hope of success, and these no surgeon would fail to look for.

Other points of interest in the case are the rapidity with which, judging from the symptoms, the cartilages were affected, the joint was disorganised and repaired, and the probable order in which the parts were attacked. The symptoms of ulceration of the cartilages date from a few days after the wetting was received. Judging from what we now know, it seems probable that even so early this most serious mischief had begun. Again, the whole period during which the patient lay in bed was five months. For a month before she got up, the startings had ceased, and the swelling had diminished. At the time of

the removal of the parts, six months afterwards, they are found entirely healed, with sound osseous union.

It is a case, too, which serves as a caution against the too common inclination to regard every disease of the knee-joint as depending upon struma. Here there was no degeneration of the bone. The affection was evidently acute synovitis, resulting from ordinary causes, wet and cold. I believe that the membrane becoming intensely inflamed, the destruction of the cartilage was commenced by its agency; that the membrane itself disappeared in the general ruin; that finally the bones were exposed, granulations were thrown out, and the osseous union between the femur, tibia, and patella was perfected.

INTESTINAL OBSTRUCTION TREATED BY CATHETERIZATION OF THE BOWEL.

By N. W. COLAHAN, M.D.

CASE 1.—On Sunday, the 1st November I was called at 11 o'clock at night to the workhouse hospital to see a man who had been admitted with obstruction of the bowels. He told me his bowels had not been moved for six weeks. He had taken eleven purgative pills, three doses of salts, and, on the day of admission, a large dose of castor oil, none of which produced any effect. His abdomen was enormously distended, hard and tense on pressure, he had stercoraceous vomiting, and was extremely weak. I ordered him a warm bath, to be followed by a purgative enema—

R. Ol. ricini, ℥i.;
Ol. terebinthinæ, ℥ij. M

to be given with warm water; beef-tea during the night. On Monday his bowels had not been moved. The stercoraceous vomiting continued, and he was decidedly worse. I ordered the warm bath to be repeated, prescribed a purgative pill containing croton oil ℥ij., followed by an enema similar to the first. On Tuesday the bowels were still unmoved; the stercoraceous vomiting had increased in frequency and amount. The pulse was almost imperceptible, and the man was evidently sinking fast. The stomach would retain neither nourishment nor medicine, enemata had proved useless, and there was but one chance left—to catheterise the bowel with the long tube. I sent for the tube of the stomach-pump, as it was the only one long enough, and passed it *per anum* to its entire length. When it reached the top of the large bowel an enormous quantity of gas which had been confined there came away through the tube with a loud roar. I then gave a strong purgative enema—

R. Ol. ricini, ℥ij.;
Ol. terebinthinæ, ℥ij.;
Ol. crotonis, ℥ij.;
Mucilagum, ℥iv. M.

followed by large quantities of warm water, and withdrew the tube and in about three minutes there was a copious evacuation from the bowels, and the man felt much relieved. Beef-tea to be continued. Brandy every fourth hour. On Wednesday the vomiting had ceased, the pulse was strong, but the bowels had not been moved naturally, and, as there was still great distension of the abdomen, I again passed the tube, and the bowels were again moved by an evacuation that lasted several minutes. From that moment the bowels began to move naturally, and the man improved rapidly, and on Tuesday, 10th November, nine days after admission, I discharged him cured.

CASE 2.—On 11th December I was called to see a woman who was suddenly attacked with convulsions. She was suffering great pain from the over-distended state of the abdomen, and the ascending colon stood out like a large tumour on the right side. It was a case that required immediate relief, as the convulsions were recurring again and again. So I ordered the long tube to be passed *per anum* to draw off the gas from the distended colon, and gave a strong purgative enema, and in the morning the convulsions had ceased and the woman was out of danger.

CHOLERA: ITS ÆTIOLGY, CONTAGIOUSNESS, AND TREATMENT.

By WM. BOYD MUSHET, M.B. Lond., M.R.C.P.,
Late Physician to the North London Hospital for Consumption, formerly
Resident Physician at St. Marylebone Infirmary.

PATHOLOGICAL APPEARANCES.

(Continued from page 6.)

In Dr. Parkes' forty-seven cases, all had vomiting and purging previous to admission into hospital. Cramps were not universally observed. There was diminution of animal heat, laborious respiration, and embarrassed action of the heart. There was no ratio between the vomiting and purging and the algide symptoms, and cases were often more malignant and more rapidly fatal with little vomiting and purging. The skin often became lighter after death, and the shrivelled appearance of hands and feet diminished. The most marked appearances in the head were venous congestion. *The lungs were diminished in weight, from 17 to 20 oz., taking European lungs as a standard.* They were collapsed, and deficient in crepitation, pale or dark, becoming lighter by exposure. Right heart filled, often distended with blood; left heart generally empty, or almost so; blood generally fluid, sometimes coagulated, dark or fibrinous; no spasm of ductus communis choledochus. *Small intestines in every case contained more or less fluid, which consisted of flocculi and a serous portion, consisting of water, salts, and a protein compound.* Urinary bladder in every case contracted. In the lungs there was remarkable want of air. In the most rapid cases, also, a want of blood in the minute texture, causing the lung to collapse when the chest was opened, and its weight to be diminished in a very great degree. Gorged and congested lungs occasionally happened; yet in some of the worst cases there was a singular deficiency of blood in the pulmonary texture. Appearances therefore satisfactorily prove that there is more or less complete failure in the transmission of blood through the lungs; but this is not due to failure of the heart, as it beats in many cases till stopped by want of blood on the left side. Moreover, the respiratory muscles are not paralysed, and the lungs can be inflated readily after death, or the patient can breathe deeply during life if told to do so. We must look, therefore, to the blood itself for arrest of the circulation through the lungs. The exuded fluids in cholera occur not apparently as secretions, but as exhalations, i.e., they are not subjected to the vital influences of cells—true secretion seems arrested. Parkes considers the cold stage the true stage, and not the initiatory one, as in ague.

In twelve carefully reported post-mortems, recorded by Mr. G. G. W. Callender, Registrar of St. Bartholomew's Hospital (Committee for Scientific Inquiries, 1854, Appendix), most of the patients dying during collapse, the rigor mortis was well marked in all, the left side of the heart contracted, the right flabby; the veins (venæ cavæ, &c.) gorged with fluid blood or soft clots, the aorta and pulmonary arteries mostly containing soft clots, or, in some cases, fluid blood. In the aorta, small in quantity. In most subjects the kidneys natural, or pale. Capillary congestion of lungs and bronchi in most cases. Mucous membrane of intestines in some cases congested, in some pale. *Lungs in some cases natural or œdematous; in two or three, red in colour, and more or less carnified.* Peyer's patches in most cases natural. Liver pale or natural. Gall bladder in most cases contained much bile. Spleen natural. Bladder contracted, and empty in all the cases which died in collapse. Brain and membranes natural in every case, and a small quantity of serum in the ventricles of the brain.

On referring to my own notes of autopsies performed on adults and children dying during collapse, I find that the whole intestinal tract may be as pale, if not paler, than in the normal condition, and that the liver, spleen, and kidneys have been found not markedly congested.

I have never seen spasm of the ductus communis. *The lungs have been at times congested more than any other organ, and I have not noticed the marked pulmonary collapse spoken of by other authors.* The most striking appearance has been the extreme fullness of the great veins on the inner surface of the thoracic and abdominal cavities. The blood on both sides of the heart mostly fluid. Gall bladder moderately full or distended, and contents natural. Bladder empty. The intestines usually filled with the characteristic fluid, and I have met with large masses of scybala in the colon, in a patient dying after copious dejections in the collapse stage.

I do not believe the effusion from the alimentary canal is dependent on a congested state of the internal organs attempting to relieve itself by increased secretion, but that it is (as Dr. Parkes observes) an exhalation arising from relaxation and heightened irritability of the intestines, which favour its egress from the vessels, and then eliminate it from the system—not an effort to throw off a poison, but an endeavour of the muscular coat of the bowels to overcome and relieve distension.

With regard to an eruption in cholera, Dr. Roupall states that an eruption has been seen in some few instances in this country, and occasionally abroad, and Rayer also mentions a roseola cholericæ, which is thus described by Erasmus Wilson: "After the period of reaction, there occurred in some patients (Paris, 1832), especially in women, an eruption, which most generally appeared on the hands and arms, and then extended to the neck, the breast, the belly, and the upper and lower extremities. At its commencement, it was characterised by patches, for the most part of an irregular circular shape, of a bright red colour, elevated above the surface, and but slightly itchy. Very numerous on the hands, arms, and chest, they were less on various other parts; in some places they were crowded together, tended to confluence, and had an appearance very analogous to the efflorescence of slight scarlet fever; in other places, the aspect of the eruption was rather like that of measles; and in others, even more like that of urticaria. I have seen this inflammation complicated with an inflammatory affection of the fauces and tonsils, and its disappearance followed by an aggravation of the general symptoms, and sometimes even by death. On the chest the spots occasionally became confluent, and gave rise to patches as broad as the hand, raised above the general level, and pretty well defined. The eruption then acquired a dirty pink, or rose colour. About the sixth or seventh day the epidermis cracked, and was thrown off in large flakes on almost all the places where the eruption had existed." ("Skin Diseases," page 155.) (See also "Guy's Hospital Reports" for 1857-8.)

Treatment.—As a prelude, it must be borne in mind that practitioners publish cases successfully treated, without statement of their intensity, or of the period of the epidemic. It is agreed by all that attacks are proportionately much less fatal during its wane.

In the premonitory, or choleric stage, before the advent of algide symptoms, sulphuric acid is, in my opinion, the most valuable medicine; but it becomes less and less useful after incipient collapse. It is perhaps, on the whole, the most reliable of any single agent, and, if serviceable, generally proves so after one or two doses, which should be given at intervals of ten minutes, to the extent of forty minims of the dilute acid in an ounce and a half of water or peppermint. If it fail to arrest the diarrhoea and vomiting, the disease often proves intractable to every remedy. At the same time, the patient should be put to bed and well covered, though in the algide stage there is a general tendency to push off the bed-clothes, for, as Dr. Parkes remarks, "cold is more grateful than warmth to the patient." Ice, iced water, or cold water, may be supplied *ad libitum*, which Professor Maclean also recommends. Cold drinks are generally eagerly desired during collapse, though Dr. Rae, of Newcastle, allowed only a limited supply of fluid, and administered opium and styptic injections. Opium is

certainly useless during the collapse stage; but Dr. Parkes speaks in favour of it, in combination with acetate of lead, calomel, creasote, and bleeding. He never found frictions, blisters, or mustard of any service in relieving the algid symptoms, though they might allay spasm; but I have found chloroform give more relief from the cramps. It only causes cessation of pain, without producing any permanent improvement. All patients died who were treated with castor-oil on the eliminant plan by Dr. Filliter and myself; and this treatment was adopted towards the end of the epidemic, at which period a large percentage usually recovers under any plan of treatment. I know nothing of the treatment by sugar which has been advocated. Emetics of mustard appear occasionally to rouse the patient; but I never observed any ultimate good from their administration. They do not allay the vomiting, which has however yielded, I believe, at times to creasote, capsicum, and calomel combined. Chlorate of potash does no harm, and perhaps no good. Salines seem to exert little action in deep collapse, but are useful in consecutive fever. They were extensively tried in the St. Marylebone Infirmary, after the formula of Dr. Stevens; but I have never seen the effect of saline injections into the vessels. They are good theoretically, but it is unfortunately all exosmosis, and Dr. Parkes relates that injections never saved one patient. Sinapisms, hot-air baths, and other external applications are of little use, and fail to warm the patient. The hot-water bath I have never seen tried, but frictions of the extremities and trunk with the hands, or turpentine or warm fomentations give ease in early stages of collapse, but are useless in its profounder forms. Large doses of chloric ether and ammonia have now and then a temporary beneficial effect. This treatment roused a woman apparently dead, but although she spoke, she sank within a quarter of an hour. I have never given trial to the sulphur treatment, so strongly recommended by the late Mr. Grove. Quinine in a few cases was of no benefit. Chalk, catechu, and remedies of this class are of course useless.

Calomel, strongly recommended by Dr. Ayre, whatever its *modus operandi*, seems at times to be of service. If not absorbed, it can do no harm, and there is little fear of its absorption causing salivation in the consecutive stage. Of course, it is mostly rejected as soon as swallowed, and no practitioner of intelligence would push its exhibition to extremes. If I have a theory, it is in favour of the mercurial controlling the capillary circulation. Dr. Ayre thought the calomel converted into grey oxide by the alkalies of the stomach; but I have found the ejecta acid. Dr. Hassall, however, says the rice-water discharges are always, as far as he has observed, highly alkaline.

In the worst cases, perhaps, Dr. Parkes is not far from the truth in asserting that one remedy is not more useful than other; but I cannot agree with Dr. Parkes, Dr. Johnson, and Mr. Sedgwick that bleeding can be of service, as the state in cholera is vastly different—altogether dissimilar—from conditions such as pneumonia, asthma, bronchitis, and other forms of apnoea, in which there is a loaded state of the right heart, a full venous system, and a mechanical impediment to the circulation through the lungs, so that carbonic acid accumulates in the blood. In cholera, on the contrary, there is arrest of oxidation, non-formation of carbonic acid, little embarrassment of the respiration, and no dyspnoeal symptoms, as the patient almost invariably lies recumbent on one side, whilst in the former diseases there is alarming orthopnoea or coma.

In future epidemics, carbolic acid and the carbolates, advocated by Dr. Sansom, deserve a trial as well as the sulphites so strongly spoken of by Dr. Polli, of Milan, and by Mr. Spencer Wells. Yet I have given the hyposulphite of magnesia in the more malignant forms of scarlatina with disappointing results. Much is also to be expected from the hypodermic employment of the alkaloids, especially of atropia and digitaline, or a combination of morphia and atropia in the manner adopted by Dr. Brown-Séguard.

Since the foregoing was written, I have to add (without discussing the theory which suggested its adoption) that

hypodermic injections of chloral, decimally diluted with water to the extent of two to ten grains, are reported to have been very efficacious in a few (nineteen) sporadic cases in Oudh. This remedy deserves, and will doubtless obtain, a more extended trial.

In addition to drugs, if the vomiting cease, pure iced milk and lime-water in small quantities may be given, if agreeable, to support the patient over the consecutive symptoms. Brandy does no good in collapse, and may prove subsequently harmful, if the patient survive till reaction. It will be gathered from the foregoing outline that the experience of one who had charge of the cholera wards in a parish of 160,000 inhabitants affords the dismal prospect that the best remedy in incipient cholera is sulphuric acid, and that in the more aggravated forms therapeutics are almost helpless. The most experienced practitioners are inclined to leave their patients unmolested, with unlimited pure water to allay the thirst, the excretions being received into a vessel disinfected by carbolic acid and sulphate of iron, or chloride of zinc; the symptoms being carefully watched that the access of consecutive fever may be, as much as possible mitigated, and the action of the kidneys restored in prevention of uræmia, success in our efforts being much determined according as the renal organs are diseased or sound. (a)

Transactions of Societies.

THE SURGICAL SOCIETY OF IRELAND.

THE Society met on the evening of the 11th December, Dr. E. HAMILTON, Vice-President, in the chair.

Mr. WILLIAM THOMSON, Surgeon to the Richmond Hospital, read a communication on

A CASE OF EXCISION OF THE KNEE FOR BONY ANKYLOSIS WITH DEFORMITY,

which will be found *in extenso* at page 26.

In the succeeding discussion,

THE VICE-PRESIDENT said the important question raised by Mr. Thomson's paper was, whether they should run the risk of a serious operation in order to cure a mere deformity. He remembered a case some years ago, in the practice of the late Mr. Symes, which made an unfavourable impression on him. The patient was a strong young woman, in good health, but having this deformity of the knee. The operation was performed of cutting out a wedge from the knee, and she died a few days afterwards. It would be a very important point if they could come to any decision as to the class of cases in which the operation should be performed, for undoubtedly it was an important matter not to allow a person to go about with a deformity if they could venture with safety to interfere.

Mr. H. G. CROLY had a case of excision of the knee-joint some three years ago. The patient was a very healthy-looking young countryman, who was recommended to come up to Dublin from Roscommon to have his knee straightened. His leg was flexed at right angles to the thigh by true bony ankylosis. Having found nothing could be done by tenotomy or forcible extension, a consultation was held upon the case, and it was considered whether it would be justifiable to amputate the limb or to excise the knee-joint. His (Mr. Croly's) opinion was against amputating the limb for a mere deformity, and he put before the patient the risk of an operation on the knee-joint, and asked him whether he would run that risk or keep his deformity. All his colleagues being favourable to the operation, and the man himself urgently desiring it, he excised the knee-joint, and he never went through the steps of any operation where he had experienced such difficulty.

(a) The injunction of the venerable Diemerbroëck, *fuga cum timore Domini copulata est prestantissimum et certissimum prophylacticum à peste*, savours of a bygone age. The true and universal preventive of cholera is to be sought, as Mr. Simon admits, less in quarantine than in national sanitation—that is, in cleanliness, interpreted in its most comprehensive definition.

The popliteal space was filled up entirely with bone. The case went on well for some time, healing so that the line of union could hardly be seen. However, an unfavourable change occurred; the man got all the symptoms of surgical fever, and died. Within the last month a similar case came to him from the country, with a view to excision of the knee-joint. The patient had lateral displacement, with bony ankylosis; but the unfavourable result of the former case made him reluctant to interfere. He remembered a case occurring in the practice of the late Mr. Hutton, where he cut out a wedge-shaped piece of bone, and a fatal result followed. Sir William Fergusson, a high authority, was of opinion that in the case of a bent knee excision of the knee-joint was the operation that should be performed. In many cases the deformity could be remedied by stretching; but in bony ankylosis excision must be resorted to, and might be justifiably undertaken if the disease had ceased to extend.

Mr. STAPLETON said it was a confusion of ideas to speak of cutting out a knee-joint where there was bony ankylosis, for in that case the knee-joint had ceased to exist, and the operation would be more properly described as cutting out an ankylosed portion of bone.

Mr. THORNLEY STOKER had had an opportunity of watching both the cases described (Mr. Thomson's and Mr. Croly's), before the operation and afterwards, and he could endorse every word which these gentlemen had said of their respective cases. As regards the propriety of Mr. Croly's operation, he had no opinion in the matter. He never saw a man more anxious for an operation, and Mr. Croly's colleagues were all of opinion that it ought to be performed. He was a healthy subject, and apparently a favourable one for operation, as was Mr. Thomson's, but there was one great difference between the two cases. The case in which Mr. Thomson operated was due to acute synovitis. She had no struma, and the fact of the disease of the joint having followed on a wetting proved that there was no constitutional taint. In the case Mr. Croly operated on, the man had been suffering a much longer period from the disease, and although at the time of his admission to hospital he did not present any trace of constitutional disease of a strumous character, still the history of the case pointed to the existence of some taint at the time the disease in the knee originated, and this might have had something to do with the difference of the result in the two cases.

Mr. BARTON said that Mr. Thomson had brought forward the successful result of an operation in a class of cases which caused great anxiety and gave rise in the mind of the surgeon to great doubts. If the operation for such deformities was open to very great doubt, perhaps the study of Mr. Thomson's case might enable them to answer the question the Vice-President had thrown out—namely, what were the circumstances in the case which would render the operation favourable, or should, on the other hand deter the surgeon from adopting it? One thing which struck him was the great rapidity of the pathological action in that case. It was only six months before Mr. Thomson excised the bone that the morbid process began; it was evident, therefore, that the process was not only acute but non-suppurative. These were the cases in which excision of the knee-joint was most favourable. The age of the patient, too, was another favourable feature in considering the propriety of the operation. He remembered the case referred to occurring under the practice of the late Mr. Hutton, and the fatal result there was due to the rupture of the popliteal artery. It had deep attachments, and the sudden straining of the limb caused the rupture of the artery; whereas, as the joint had only recently been fixed in Mr. Thomson's case, that danger could hardly arise. He could not agree with Mr. Stoker in thinking that the urgent demands of the patient should compel a surgeon to operate in a case which would probably end fatally.

Mr. STOKER explained that all he meant to say was that when the question of operation was an open one the choice of the patient had some influence.

Mr. BARTON did not think that the wish of the patient ought to have as much influence as it sometimes had in these cases. Surgeons ought to make up their minds on more certain data. If the successful result of Mr. Thomson's case led them to extend the practice more widely to cases of a more chronic character it would be a great misfortune, but it would be of great value in inducing them to act in cases so suitable for operation as his was.

Professor STOKES: All the pros and cons in connection with the operation were most anxiously and carefully considered, at not one, but many consultations, and it was with the

high advice of their revered colleague Dr. Adams and the unanimous opinion of Mr. Thomson's colleagues that it was a desirable operation to perform that he undertook it. We had a case in which the disease was very rapid, in which the patient was young, and the deformity so great as to render her a perfectly useless member of society. There were four courses open: One was to make forcible extension; another to adopt the operation which Professor Grosse recommends so strongly; the third was to amputate the limb; and the fourth was to perform excision. The case under Mr. Hutton to which Mr. Barton alluded I have often heard the late Professor Smith dilate on in his lectures, and he used to warn us never to perform the operation of forcible extension if bony ankylosis existed. With regard to Professor Grosse's plan of drilling holes through the bone, it was not desirable. The third course, amputation, had to be set aside, and therefore nothing remained open but the excision of the bone. Of course it was a hazardous operation, but I do not think with Mr. Croly that because one case proved unfortunate it should deter us from performing the operation when a suitable case arises. If such considerations influenced surgeons, the operation of ovariotomy, now well established, would never have been so. The unfortunate results that attended the early performance of the operation would have prevented it being ever brought into practice had surgeons been influenced by that idea. There was no question as to the propriety of the operation in this instance, and we must all congratulate Mr. Thomson on the success of his first excision of the knee-joint.

Mr. THOMSON in reply said, with respect to Mr. Stapleton's objection to the unsuitability of the term used in his paper, he was quite aware there was no knee-joint, and he used the term merely in a familiar way, so that the part that was engaged might be localised. The whole tenor of the discussion had taken the turn which the Vice-President had given it at first—namely, what were the cases in which this operation would be justifiable? He agreed with what had fallen from Mr. Barton and other speakers, that the cases for this operation ought to be particularly chosen, and that probably in cases in which the ankylosis had arisen from some affection of the joint which was clearly strumous, and where the constitution of the patient was more or less engaged, an operation so serious would not be desirable. But in this case, as he had stated in the paper, he had examined carefully into the previous history of the patient, and her family history, and was satisfied that there was no strumous taint whatever, and that the condition of the knee-joint had simply arisen from a local disease, and that if there ever was a case in which the operation of excision should be undertaken, it was this one. He agreed with Mr. Stokes that the want of success which may attend operations at their outset ought not to deter surgeons from pursuing them. Ovariotomy and other operations were at their outset attended with but a very limited amount of success, but as they had gone on the surgeons had learned from each successive operation, and the proportion of success in the later cases was far greater than in the earlier ones. Since he had written the paper he had looked into Mr. Grosse's book, and found it stated that Mr. Buck, whose operation he followed in this instance, had performed the operation ten times, and had eight successful results, two of the cases dying of pyæmia.

The Society then adjourned.

SIR WILLIAM JENNER is to be President of the Pathological Society of London again.

THE third meeting of the Dublin Obstetrical Society was held in the College of Physicians, on Saturday last, when the following communications were set down for reading:—

Dr. Johnston, "Clinical Report of the Rotunda Lying-in Hospital for the Year ending November, 1874." Dr. T. More Madden, "Case of Metro-peritonitis following Vaginal Injection." Dr. Denham, "A Case of Extra-Uterine Fœtation." Dr. Nicolls (Longford), "On Protracted Labour, Hour-glass Contraction, Hæmorrhage, and the Introduction of the Hand into the Uterus."

ARMY MEDICAL REPORTS.

I.

THE Army Medical Department Report for the year 1872 lies before us. It is the 14th volume issued by the department, and consists of 557 pages, many of which are composed of carefully prepared tables. It is a most creditable production, and well worth perusal by all medical men interested in public medicine. As far as page 55, the book is devoted to the health of the troops serving in the United Kingdom; then, up to page 71, the health of troops in the Mediterranean is considered; from page 72 to page 76, the work treats of the troops in Canada; from 76 to 80, of the troops in Bermuda; from 81 to 90, of those in the West Indies; from 90 to 93, of those serving in Western Africa; from 93 to 98, of the troops at the Cape of Good Hope; from 98 to 108, of those in Mauritius; from 104 to 112 about those in Ceylon; from 112 to 128 concerning those in China; and from 129 to 211 we have an important history of the health of our troops in the East Indies. The work is enriched with an appendix, wherein Dr. Edmund Parkes writes a Report on Hygiene, and where various essays are printed by army medical men of great experience upon consumption, water-supply, gun-shot wounds, heart disease, dengue, chloroform, and numerous other important points in practice.

Beginning at the beginning, we find that during the year 1872 no less than 92,218 men served their country in the United Kingdom alone. These troops seem to have been very healthy, for, in 1872, out of 1,000 men, 784.3 were taken into hospital, of whom only 7.95 per 1,000 died, a very low death-rate indeed. Of the febrile cases, 4,502, admitted into hospital in 1872, only 67 died; and of 14,044 styled constitutional diseases, 253 died out of the whole force. The ratio of admissions from the febrile group was highest at the dockyards, seaports, and manufacturing towns, and lowest at the camps and London and Windsor. The febrile diseases refer to eruptive fevers, continued and paroxysmal fevers, to influenza, erysipelas, and other febrile cases. The consti-

tutional group contains rheumatism, syphilis, scrofula, phthisis, scurvy and purpura, anæmia, &c.

CONSTITUTIONAL DISEASES.

The ratio of cases of scrofula, phthisis, &c., admitted per 1,000 into hospital seems to vary but little in various towns, the extreme number being 16 and the lowest 11. The admissions per 1,000 for syphilis, however, seem in 1872 to have varied greatly in different localities. Thus, in seaport towns (p. 6), 74 is the number given; in dockyards and arsenals, 67; in camps, 78; in large manufacturing towns, 126; in London and Windsor, 230; in Dublin, 198; in remaining stations, 85.

ERUPTIVE FEVER

Were much less prevalent than in 1871, notably variola and scarlatina, there being 131 admissions for small-pox, with 14 deaths. Of 53 admissions for scarlatina, only 2 died, and of 204 admissions from measles there were 4 deaths. Typhus fever caused 6 admissions and 2 deaths; enteric fever caused 22 deaths. In some places it was very fatal. Thus, of 10 admissions in seaports, 6 died; of 7 in dockyards, 3 died; of 8 in camps, no less than 7 died; whereas of 8 admitted in London and Windsor, only 1 died.

CONTAGIOUS DISEASES.

It appears that "syphilis" was more prevalent in 1872 than in 1871 at seaports, camps, London and Windsor, Dublin, and the remaining stations, and less at the dockyards and arsenals, and large manufacturing towns. The result for the whole force in the United Kingdom was an increase of 9.73 per 1,000 in the ratio of admissions, 6.84 of that amount being in primary syphilis, and 2.88 in secondary syphilis. The ratio of admission at London and Windsor, and Dublin, was nearly three times, and that at the large manufacturing towns, though reduced, nearly twice that at the seaports, dockyards and arsenals, and camps.

In places where the Contagious Diseases Acts are carried out, which are Devonport and Plymouth, Portsmouth, Chatham and Sheerness, Woolwich, Aldershot, Windsor, Shorncliffe, Colchester, Winchester, Dover, Canterbury, Maidstone, Cork, and the Curragh, the admissions per 1,000 men into hospital for primary venereal sores are given in a table in page 8. It is there stated, for instance, that in Devonport and Plymouth, in 1867, the figure was 76; in 1868, 66; in 1869, 74; in 1870, 58; in 1871, 50; and in 1872, 59. Portsmouth is stated to have had in 1867, 116 venereal sores per 1,000 men; and in 1872, only 40.

In other large towns and places not under the Acts, London had in 1867, 163 cases of venereal sore per 1,000 men, and in 1872, 199; Manchester in 1867, 177, and in 1872, 98; Dublin in 1867, 129, and in 1872, 165. Taking all the stations in each group together, the ratio of admissions for primary venereal sores per 1,000 of strength was 54.18, at those under the Contagious Diseases Acts, and 123.15 at those not under the Acts.

In page 10 are some interesting tables concerning the amount of gonorrhœa and other contagious diseases at the different stations. From one of these tables we find that in stations not under the Acts, there were

108.6 cases of venereal sores per 1,000 of strength, in 1864, and 112.5 cases of gonorrhœa. In 1872 there were 123 venereal sores, and 105 cases of gonorrhœa per 1,000. Again, in stations under the Acts, there were 120 cases of venereal sores in 1865, and only 54.2 in 1872, whereas cases of gonorrhœa have not been so much altered, being 140 in 1865 and 104 in 1872 per 1,000.

Here are the remarks made, we presume, by Dr. Balfour: "In 1864, the year in which the Contagious Diseases Act was first passed, and the year before it came into operation, the admissions into hospitals at these 28 stations (under the Acts now) were in the ratio of 108.6 for primary venereal sores, and 112.5 for gonorrhœa per 1,000 of mean strength. In 1872 the admissions were 54.2 and 104 respectively at the 14 stations under the operation of the Act, showing a reduction of 54.4 per 1,000 in primary venereal sores, or that form of disease which is likely to produce great constitutional deterioration, and 8.5 per 1,000 in gonorrhœa. Again, if the average of the eight years during which the Acts have been in operation, be taken, it will be seen that at the stations not under the Act, in an average force of 32,500 the ratio of admissions for primary venereal sores was 103 per 1,000, and for gonorrhœa 111.9 per 1,000; whilst at the stations under the Act, in an average force of 31,000 men, the proportion was 63 and 114 per 1,000. These results show a difference in favour of the stations under the Acts of 40 per 1,000 in the case of primary venereal sores, and an excess of 2.9 per 1,000 in cases of gonorrhœa. Or again, if the results for 1872 alone be compared, they show the admissions at the stations under the Acts to have been 54.2 per 1,000 for primary venereal sores, and 104 for gonorrhœa; whilst at those not under the Acts there were 123.1 and 105.9 per 1,000 respectively, showing a difference of 68.9 per 1,000 in venereal sores, and 1.9 per 1,000 in gonorrhœa, in favour of the stations under the Acts."

Such are the remarks made by Dr. Balfour, and they will, of course, be canvassed very freely at this time, when feelings run so high both within and without the precincts of the profession upon the very interesting and important question of how to diminish venereal contagion among our military and civilian population. It would not become us to decide all at once so intricate a question as that involved in the figures before us. That the health of the troops in as far as venereal contagion is concerned is better in France, Belgium, and some parts of Germany, where similar acts obtain, seems clear enough from statistics. What is not clear is whether towns like Paris, Berlin, or Vienna are less free from venereal contagion than London, Manchester, or Glasgow—in a word, it is not clear whether in keeping military men supplied with healthy prostitutes, other people have not given civilians the habit of having recourse to prostitution.

Notes on Current Topics.

Drinking Human Blood.

It appears in the heartrending account of the sufferings of the survivors from the wreck of the *Cospatrick* that on

the 23rd of December four men died, and the thirst of the remaining unfortunates was so great that they drank some of the blood of the dead men. Horrible as the idea is, there is no clear reason why there should be much danger to health apprehended from so doing. Some nations have delighted in the blood of horses, and cannibals are said to boast of drinking the blood of their enemies.

Lead Palsy.

In paralysis caused by lead, says Dr. Charcot (*Le Progrès Méd.*, Dec. 26), a lesion of the peripheral nerves takes place. This was first pointed out by Dr. Lancereaux. The muscular atrophy caused by lead seems then to be analogous to those seen in rheumatism or wounds, in this respect, that it seems to depend also on a lesion of the peripheral nerves, and this is more marked when it is seen that Faradic electricity fails to cause contraction.

Registration of Births.

THE new Act for the Registration of Births and Deaths in England has just come into operation. Medical men are now compelled to grant certificates of death, if they have last seen the patient. In the case of a birth, information must be given within forty-two days, and of a death within five days.

Dr. Stark.

A PENSION of £130 a year has been granted to Dr. Stark, Regist ar-General of Scotland.

Rational Treatment of Consumption.

DR. PIETRA SANTA (*La Tribune Méd.*, No. 329) sustains the doctrine of the curability of phthisis, after having combated the theory of the germals of cellular proliferation, and the fatalism of the school of Broussais.

In his view, phthisis is an affection essentially general and constitutional, a profound alteration of the nutrition, a disease of the blood. There can then be no panacea for a disease which is a symptom of an enfeebled vitality, and of which the various phases of evolution form as many distinct morbid entities. There can be no antidote for a morbid diathesis which pre-exists before the anatomical lesions of a local nature which characterise the affection.

The only specific for phthisis pulmonalis is the intelligent association, reasonably applied, of that collection of medications the value of which has been recognised by clinical experience, and which are summed up in these precepts:—

1. To summon to our aid, during every stage of the disease, the uncontested resources of private hygiene (hygiene and moral treatment, pure and often renewed oil, tonic régime, moderate exercise, milk diet).

2. To utilise the modifications impressed on the economy by mineral waters (sulphur, arsenical, and chlorine).

3. To invoke the salutary effects of the change of climate and emigration (stay in the temperate southern climate in winter, in the mountains in summer).

4. To neutralise the morbid ferments which purulent absorption causes in the organism, when the softening and evacuation of tubercle takes place. This capital medica-

tion, which for the past ten years has furnished the happiest results, is obtained by the administration of the hyposulphites and neutral alkaline sulphides.

A True Nobleman.

MR. ATTWOOD, of Cheshunt, has just died. He was that grand anonymous benefactor of hospitals who used to send £1000 gifts as it were from heaven.

The New Irish Public Health Act.

LAST week the sub-sanitary officer at Galway had two prosecutions under the Sanitary Act, the first which were brought in this county. The persons summoned were farmers living immediately outside the town, and the cause of complaint was that of having dungheaps in their yards so convenient to the doors that it became dangerous to health. *Dr. Clayton stated to the bench that he had been threatened by the inhabitants of Castlebar, who said if they caught him in the locality for the future they would destroy him.* When the result of the case was stated to one of the defendants, who spoke but Irish, he said, "Fined for making my own manure in my own yard. Well, that is d—d bad law, but like all the rest the poor man gets in Ireland." He grew infuriated on the table, and was removed.

Hypertrophy of the Anterior Lip of the Uterus.

DR. BLOX (*Le Mouvement Médical*, Dec. 26) reports on a case where an accoucheur, Dr. Calmeil, was called to a labour by a midwife, to a woman in labour already twenty-seven hours. A fleshy tumour, consistent and depressible, protruded from the vulva; the fetal head was placed above and in the position left occipito-iliac, and delivery was effected. The tumour was the size of a foetal head, and hung from a voluminous pedicle, following which with the fore-finger, the anterior lip of the os uteri was reached. The placenta had come away entire; the uterus had commenced to contract. Dr. Calmeil placed a waxed thread around the pedicle, which he tied tighter daily. On the fifth day this pedicle was only the thickness of the little finger. In a few days the pedicle was cut through. The tumour thus removed was solid, covered on its external surface with a strongly adherent mucous membrane, and formed of dense fibres traversed by numerous vessels. Dr. Blox had observed fifteen years ago an analogous case in a young woman, who had been long in labour when he was called in. A tumour like that described hung from the vulva: the forceps terminated the labour, and the tumour retired into the vagina, where it became so atrophied that in a month it was barely possible to recognise an hypertrophy of the anterior lip of the os uteri. Dr. Verneuil mentioned the case of a woman who had died from total obstruction of the vagina by a soft tumour which was found to be the anterior lip of the os uteri.

Typhoid Fever.

WHILE the prevalence of this mysterious affection is so marked, and its victims are daily and often so suddenly carried off, it is a matter of intense interest to acquire reliable information on the possible sources of such an

increasing pestilence, and more particularly as to its means of propagation. Amongst the readers and supporters of this journal there are members fitted by experience and means of observation to give valuable information, and to bring forward cases illustrative either of total apparent means of explaining the origin of the affection, of assigning its origin to a certain independent springing into existence, or of its contagiousness.

So great is the severity of this scourge of both the poor and wealthy classes that, we believe, no subject could be of greater interest to the public and to the profession, and we would therefore request members of the profession throughout the country, and more particularly those in isolated country districts, to forward for publication in our columns any illustrative cases either in support of or against its contagiousness, or its spontaneous origin. We shall be glad to give the views of all contributors.

We find such authorities as Bretonneau and Gendren believing that the poison of typhoid or true enteric fever can adhere to the clothing, and so be carried as *fomites*, and spread the disease. We find also so accurate an observer as Dr. Wm. Budd maintaining that the contagious nature of enteric fever is the "master-truth in its history," and Sir Thos. Watson endorsing this view; Trousseau stating in his lectures, when tabulating a number of reports, that "the contagious nature of dothinenteria is incontestable;" while, on the other hand, Andral, Chomel, Stuart, and others doubt if contagion really exists; while hospital experience seems on the whole to contradict the view of its contagiousness.

There seems no doubt that lately isolated cases of great intensity have arisen without apparent cause, and therefore information from observed and closely investigated cases would be valuable, and of great interest. It might be suggested to adopt the following headings:—

1st. Cases illustrating contagion (1) from the person; (2) from *fomites*; (3) from stools.

2nd. At what stage of the disease did contagion seem most active?

3rd. In country districts, did enteric fever seem to arise from contact with excremental poisoning, or from excremental fermenting emanations, where no typhoid stools could have had existence, where contagion was not possible, and where no typhoid case had been in the proximity?

Reports on the subject, restricted to true typhoid, or enteric fever, particularly from the Irish Poor-law districts, would, we are certain, be of much value.

Medical Missions.

THIS subject is thus treated in a recently published address by the Bishop of Kaffraria, Dr. Callaway, who has long been engaged in the work in South Africa, and is now in England for the purpose of urging the claims of his newly created diocese on the liberality of the English public.

"The Hospital System must be completely carried out. For this purpose friends in England sent me about £300, and £200 were contributed by colonists. This sum, with accumulated interest, now amounts to over £600; and since I came to England I have received nearly £60 more. This will be sufficient for the necessary building and furniture, but will leave nothing for the current expenses. The Natal Govern-

ment, on my application, had agreed to place £100 a-year on the estimates for this purpose, but this sum is not transferable to Kaffraria.

"It has been suggested that an appeal might be made to medical men to aid this mission, which is headed by one formerly in the profession. Medical men may well be asked to give to this especial department. They are, I know, great givers in their own circles, if not of money, of time and talents, and often of money too; and from a scanty purse not only provide the medicines they prescribe, but also the wine and nutriment without which mere medicines would frequently effect nothing.

"Medical education acts on the mind in a manner peculiarly calculated to make an efficient missionary. I know it has been said that it tends to produce scepticism—that dealing as the physician does with natural facts, and trusting to bring about results by attention to surrounding circumstances, and obedience to natural laws, he may be tempted to overlook the Great Author of Law. But there is no more necessary tendency in the study of medicine to produce such a result than there is in the study of any other branch of science. Unsteady, one-sided minds may go wrong anywhere, even in the study of the most strictly religious subjects; and if it be true that 'the undevout astronomer is mad,' much more true is it that he is mad who can study the human body, in health and in disease, and can remain an undevout looker-on, or can irreverently refuse to believe in the Great Designer. And men of the highest order of mind have found it possible to penetrate to the very depths of medical science, and to add largely by their labours to medical knowledge, and at the same time to be devout worshippers of God, and to retain unsullied their faith in Christ. I shall never forget the effect produced by one, who has since attained to the highest position in the profession—I mean Sir James Paget—when, as a comparatively young man, he broke through the ordinary cold routine of the Introductory Lecture at St. Bartholomew's, and told the assembled students, and men grown grey in their profession, what a high and holy calling that of the physician is. And I believe no heart remained untouched as there thrilled from his eloquent lips the words of good old George Herbert:—

'Man is the world's High Priest: he doth present
The sacrifice for all; while they below
Unto the service mutter an assent,
Such as springs use that fall, and winds that blow.'

"The physician is only a little less the delegated minister of Christ than the divine. It may be truly said that the priest and the doctor were united in our Lord; the healing of bodies and the healing of spirits was His mission. He came to heal all the ills which sin—that is, deviation from all-wise laws—has introduced into the world; and whilst it is well that there should be a division of labour, yet the divine would more effectually do his work if he were acquainted with medicine, and the physician would more effectually do his if he regarded himself as a humble follower in the steps of the Great Physician, the Saviour and friend of man, and made the healing of diseased bodies the means of leading his patients within the more sacred precincts of the temple, where there is healing to be found for spiritual maladies.

"The physician studies an organised body with all its wonderful complications in health; he sees it in disease, and watches disease in its progress as one of the evidences of the terrible power of law, which admits not of deviation from strict obedience without inflicting punishment; and yet he watches at the same time the self-renovating power of the organisation, which counteracts by a higher law the effects of disobedience, and himself coming in with medicines, as with grace, and so interfering with and sometimes succeeding in entirely preventing what would naturally result from unrestrained, uncounteracted law-operation. The devout, intelligent physician should be a walking, living example of the Christ.

"Then the physician is trained to seek truth as truth for truth's sake, without any strong *a priori* prejudices, or a too great disposition to listen to the mere dicta of other men, or a too great servility to the opinions of a dead antiquity. He is of necessity forced to live in the *now*; he is practical rather than theoretical, and values a theory not for its mere beauty and consistency, but for its practical benefit, in enabling him to cope with diseases, and to alleviate suffering.

"Then his system is elastic. He has learned to deal with disease, not as though it had one stereotyped form fully represented by a name, but as ever varying, with infinitely minute shades of difference, in relation to the constitution and previous

history and surrounding circumstances of the patient. So he will be prepared to see in spiritual matters the same ever-varying character; he will regard sin as spiritual disease, and not expect to find it an invariable known condition, requiring an unvarying known system of treatment. No one is more likely to comprehend than the well-trained physician.

"Might not the medical profession yield me for Kaffraria a man of skill and learning as a physician, and of deep religious sensibility; one who loves his God and his profession too well to seek for worldly gain or honour, who might unite with me at the Central Station? His work would be, to heal disease; to teach the elements of medicine to those, white or coloured, who were being trained for Holy Orders; to investigate the fauna and the flora of the country; and to make such inquiries into the system of the native doctors, and the remedies they employ, as might enable him, probably, to add valuable medicines to our own materia medica."

The Treatment of Lupus.

ACCORDING to Dr. Lailler, of the Saint-Louis Hospital (*La Tribune Méd.*, No. 329), everyone knows what a terrible disease lupus is. His general treatment consists in cod-liver oil associated with the iodide of iron, a tablespoonful of the former and half of the latter, taken in the morning, fasting, or before dinner. A little quinine wine is also given, and iodide of potassium is very frequently added, in case the lupus may have any affinity to syphilis. It is especially in lupus exedens that this is indicated. Appropriate mineral sulphurous waters are of great assistance, and sea-bathing. The topical treatment in lupus erythematosus is emollient and calmant: poultices of starch, or astringents with a few drops of perchloride of iron mixed. In cases of papulo-erythematous and tuberculous lupus, when not ulcerated, he advises caustic iodine in the form of five grammes of iodine and five grammes of iodide of potassium in ten grammes of distilled water. When hypertrophy is added to this variety of lupus, M. Lailler makes use of the iodhydrargyrate of iodide of potassium ointment. In simple ulcerated lupus, it is important to make, with care and precaution, washings which do not excoriate or produce bleeding, and to dress with the preceding ointment. If this be too exciting, it may be suspended and replaced by carbonate of lead ointment.

In lupus exedens the use of iodoform is doubly advantageous, as it modifies, and is an anæsthetic. If it do not succeed in two or three days in arresting the progress of the disease, we must not hesitate to have recourse to truly active caustics, such as mercurial ointments, Vienna paste, or Filho's caustic. When Vienna paste is used the eschar produced should be dusted with quinine powder. And Dr. Lailler insists on the use of iodide of potassium in lupus exedens.

Syphilitic Infection.

DR. HOURTELOUP read at the Société de Médecine Légale (*Le Mouvement Médical*, Dec. 26) a report on the case of an individual accused of having given syphilis to a little girl, two and a-half years old, and to a young boy, her brother, aged six and a-half, the latter having also been the victim of an *attentat à la pudeur*, of which the syphilis, as the accusation alleged, was the consequence. Here are the conclusions of the report: As to the little girl, there seems, according to the practitioner who wrote to the society, desirous to be enlightened as to its views before the court, to be nothing more than simple vulvitis.

With regard to the brother, Emile E.—1. It is certain that he presents some secondary syphilitic accidents, and the members of the society admit this. 2. His syphilis is not hereditary, and has been contracted directly. It is a pity, however, that under the report on hereditary transmission, the documents given by the practitioner are not satisfactory. M. Cornil, on this head, makes the remark that if there were here a question as to hereditary accidents, the syphilis would be characterised by marks different from what it now shows, and that there would be visceral or osseous lesions to be remarked, which is not the case. 3. The circumstances indicated by the boy, Emile E., are contrary to what generally takes place in such attempts. Resting on the question of facts, and on proofs, several members demand of the honourable reporter to suppress his proposition, which appears to them, if not hardy and rash to decide, at any rate, useless for the moment. 4. B., the accused, according to the report of the practitioner, has no actual sign of syphilis upon him. 5. The careful examination of B. does not permit the society to conclude that he could have been able in the month of July last, two months before accusation, to communicate syphilis, since the man presents absolutely no symptom or trace of syphilitic lesion.

The Adulteration Act.

THE Society of Public Analysts has agreed on the following rules to be adopted as a guide in determining whether articles are pure or not:—If food or drink contain any ingredient injurious to health, or any substance that sensibly increases its weight, bulk, or strength, unless such substance be necessary for the manufacture or preservation, and be acknowledged at the time of sale. If any important constituent have been wholly or in part abstracted, without this being mentioned. If it be a colourable imitation of, or be sold under the name of another article. In such cases the article is to be called adulterated. In the case of drugs, they are adulterated when retailed for medicinal purposes under a name recognised in the British Pharmacopœia and not equal in strength and purity to the standard, or when sold under a name not recognised in the Pharmacopœia and not coming up to the standard they profess to follow.

Arterial Embolism.

DR. MOULARD MARTIN (*Le Mouvement Médical*, Dec. 26) mentions the case of a lady, aged 48, for some years affected with blowing murmur at the apex, with the systole and palpitation. One day she had violent and sudden pain in the right leg, extending from the great toe to the knee, chilliness, insensibility, and paleness of the foot, with absence of arterial pulse in it. Above the knee the member preserved its sensation. The diagnosis was arterial embolism from cardiac clot. Pain was diminished by friction with chloroform liniment. On the next day sensibility returned, but incompletely, at the level of the calf, but the foot remained cold and insensible. In the evening the calf had a certain amount of tension and pain. The next day the pain in the calf still continued, but was limited to the internal and inferior portion. Under the fingers were felt some obliterated venous branches; there was then in this patient phlebitis of the popliteal region

and arterial embolism of the foot. There is here a singular coincidence between these two accidents, although the phlebitis was developed only forty-eight hours after the first accident.

Dr. Dujardin-Beaumez, in remarking on this case, said that in gangrene from arterial obliteration there are two categories: in the one the obliteration is slow, incomplete, and then there is no swelling; in the other, the obliteration is sudden, and then there is swelling of the whole limb. M. Maurice Raynaud, in his article in the *Nouveau Dictionnaire*, has well pointed out the difference between sudden and slow obstruction of arteries. In the cases which M. Dujardin-Beaumez and M. Vidal have observed, the arterial obstruction was complete, and in both cases the swelling was present.

Longevity of Statesmen.

MR. GLADSTONE is now sixty-five, and Mr. Disraeli has attained to the good old age of sixty-nine.

Pseudo-Hypertrophic Paralysis.

DR. CHARCOT (*Le Progrès Médical*, No. 52, 1874) says: that pseudo-hypertrophic paralysis is met with especially in young children, but may occur also in adults. The first stage lasts only a few months, and is characterised by a paresis of the lower limbs, owing to the weakness of some muscles, which at this stage may be even atrophied. In the second period, much longer than the first, the paresis tends to become generalised, and the affected muscles, especially of the calf, augment in volume. Dr. Charcot is not inclined to consider the point of departure of this lesion to exist in the nervous system or the spinal cord; it is in the muscle itself that we must look for the cause. What is most striking in the muscles in this disease is that the three plates of connective tissue, which in health scarcely separate the muscular fibres, are replaced by thick plates, which sometimes equal in diameter those of the muscular fibres. The interposition of adipose cells marks a new phase in the process; they gradually become substituted for the muscular fibrillæ, especially when the augmentation of volume of the muscle is very pronounced. With regard to the muscular fibrillæ, the alteration which ends in their complete disappearance is seen from the very first, when the connective tissue commences to become hypertrophied, and when fat cells have not yet appeared. The diameter of the fibrillæ becomes much reduced; many of the fibres are so atrophied that the greatest attention is required to distinguish them in the thickness of the interstitial tissue; the greater part of them preserve unto the last limits of emanation striation well marked. Neither the sheath of the sarcolemma nor the nuclei are altered. We cannot fail to be struck with the analogy existing between such muscles and that disease which is described when attacking the viscera as cirrhosis. The history of pseudo-hypertrophic paralysis presents an example of generalised myopathy, developed without any influence from the nervous system.

DR. MAGNAN, of Paris, has had a prize of £100 granted him by the Académie des Sciences for his experiments on dogs.

Biliary Calculi.

DR. LABORDE (*Société de Biologie*) asserts that morphia and hydrate of chloral administered together form the best drugs in hepatic colic, as they both produce anæsthesia and destroy the spasm of the canals, causing at the same time distension of the ducts with bile which by its *vis à tergo* sweeps away the stones into the intestina.

Anæsthesia in Labour.

DR. FRIEDLANDER (*Deutsche Kl.*, No. 30, 1874) has obtained, by rubbing with chloroform and ether, in the proportion of one of the former to two of the latter, total cessation of the pains of labour in many instances.

The Fixing of Sanitary Salaries in Ireland.

THE Local Government Board has evinced admirable firmness, and at the same time commendable moderation, in dealing with those boards of guardians who have endeavoured to defeat the operation of the Public Health Act by fixing nominal salaries for their officers. We noted last week that they had put their foot down upon the policy of the Dublin Corporation, and they have since followed suit with the Cork Corporation, and the guardians of Waterford, Kilkenny, Cavan, Longford, and other unions. In every instance they have previously invited the guardians to a reconsideration of the scale of payment, and have a second time appealed to them to be reasonable, and not compel them to act decisively in the matter; but in almost every instance these appeals have been entirely fruitless, and the guardians, having committed themselves to a policy of obstruction, have with characteristic stupidity refused to reconsider anything. Some of the boards have endeavoured to satisfy their own vanity and escape from the humiliating alternative of submission by disputing the authority of the Local Government Board. The South Dublin Union Guardians fled to counsel to advise them as to their liability to pay, and received for their money the information that "it was not possible to say that the matter is free from doubt;" and that "any order by the Local Government Board for payment of the salaries in question out of the poor-rate would be *ultra vires* and illegal." This method of dealing with the matter has been very fortunate for the medical officers, for it has enabled the Local Government Board to grant much more nearly adequate salaries than the guardians would have voted.

We cannot withhold from the Local Government Board the testimony of our unqualified approval. We express this feeling not because they have granted our constituents a few insignificant pounds, but because they have shown themselves to be earnest and liberal-minded in the carrying out of the functions confided to them by the country.

Prof. Mastin on Dilatation in Stricture.

We have been favoured with the following extract from a letter of Professor Mastin to Mr. Teevan. Coming as it does from a distinguished American surgeon, who has had great experience in the treatment of stricture, it will not fail to receive the attention it deserves.

"On general principles I am an advocate for dilatation

whenever it can be done; failing in that, I prefer internal urethrotomy: to this date I have performed that operation 202 times without an accident or any unpleasant result. It is true I have been forced to repeat the operation a second time upon a few cases where I had been negligent in not making the incision free enough in the first operation. Divulsion has not afforded me satisfactory results, and I now seldom if ever use it."

Human Spontaneous Combustion.

THE cases of alleged spontaneous incineration of the human body which have been recorded from time to time may be grouped with those of *morbus pediculosis* and of cured hydrophobia, to be accepted with hesitation by the profession. Although Charles Dickens, by his narrative in "Bleak House," has popularised the idea that such an occurrence is possible, it has been recently pronounced with unchallengeable authority that spontaneous combustion of the human body is impossible and incredible.

M. Chassaniol, of Brest, has recently presented to the *Société de Chirurgie* a communication on this subject, which has been reported upon by M. Horteloup.

After having shown that no person worthy of credence had ever been present during a spontaneous combustion, and that in consequence science possesses no authentic facts on the subject, he points out that it has been demonstrated that dead bodies or portion of the same, immersed for a longer or shorter period of time in spirits of wine, burn with great difficulty. It has also been attempted without success to set fire to the expired air in animals into whose veins ether and alcohol have been injected.

Spontaneous combustion has also been explained as the result of the action of electricity. It has in addition been attributed to the presence in the human body of a gas inflaming spontaneously on the approach of a light; but precise analyses demonstrate the absence of the phosphurets of hydrogen in all parts of the economy. Of late years it has been sought to refer the occurrence of spontaneous combustion to the same causes as in the case of spontaneous inflammation of various porous bodies, such as straw, hay, flax, &c. Here, again, the comparison is impossible, since combustion is due in these cases to the influence of chemical phenomena, the conditions of which are not found in the human organism.

It is thus seen that it is impossible to form any theory which shall admit spontaneous combustion. M. Horteloup does not conclude that the idea is to be entirely rejected; he simply maintains with Tardieu that it is not theory and experiment to which appeal should be made, but rather observation.

Poisoning by a New Hydro-carbon.

"ODONTOCROLL," or "carvocroll," is a heavy, oily liquid, of smoky odour and taste, and has been introduced in the dental market as a local anæsthetic for toothache. The patient was the inventor of it, and he claimed for it great efficacy as an anæsthetic in toothache, and his narrow escape from fatal poisoning is recorded in the *Philadelphia Medical Times*.

"The inventor and a friend met in the chemist's laboratory, and tested the drug by placing a few drops upon smoking tobacco and inhaling the vapour. He placed ten drops in his pipe, and, having smoked in the usual manner for a few minutes, poured ten more drops in it. After puffing a few times, he suddenly dropped, insensible, upon the floor, but in a few seconds revived entirely, and insisted upon resuming his smoke. To this his friends objected, and, during the discussion following the refusal, he again became insensible. They then removed him about two blocks, and on the way thither he fell, "collapsed," two or three times. An hour afterwards, says the writer, while I was listening to his story, he fell upon the floor again, unconscious. Upon examining him during his fall, I found the countenance somewhat dusky, the pulse normal in force and frequency, all the voluntary muscles relaxed except the abdominal, and the pupils responding quickly to light. I endeavoured to arouse the breathing, which was completely suspended, by placing one pole of the battery over the right phrenic nerve, and the other over the stomach, using the current from one cell, interrupted and secondary. The electricity did not seem to quicken the return to consciousness or respiration. Another physician was called in. He advised the administration of brandy, of which about half an ounce was given. The attacks gradually became less frequent, and, after some time, gave premonitions of their approach by grimaces and bodily contortions, which were invariably followed by the insensibility. In the morning he reported himself as feeling as well as usual, though somewhat weak and sore from his falls and struggles on the way home.

"The unconscious state lasted usually from twenty to thirty seconds, came on suddenly, and passed off as quickly as it came on. During this time respiration was entirely suspended, and all sensibility lost. The conjunctiva and dorsum of the tongue were repeatedly touched without producing any reflex muscular action, and his appearance was that of a person in a state of complete anaesthesia. While conscious, he acted as usual in perfect health, nor was he himself aware, by any premonitions, of an impending seizure."

Royal College of Physicians of London.

THE lectures of the present year will be delivered at the College on each of the following Wednesdays and Fridays, at five o'clock, as follows:—

The Goulstonian, by Dr. R. J. Lee, on February 19, 24, 26, subject, "On Puerperal Fever;" the Croonian, by Dr. Greenhow, on March 3, 5, 10, subject, "On Addison's Disease;" the Lumleian, by Dr. Beale, on March 12, 17, 19, subject, "On Life, and on Vital Action in Health and Disease."

Testimonial to Dr. Apjohn, Professor of Chemistry in Dublin University.

It has been resolved to present a testimonial to Professor Apjohn on his retirement from the Chair. Dr. Apjohn has for so many successive years been the accomplished and successful teacher of large classes of students in theoretical and practical chemistry, both in

the Royal College of Surgeons and in the University of Dublin, that it is needless to enlarge upon his merits. In order to allow of all his former pupils and admirers participating equally in the testimonial, it has been resolved to limit the subscription to one guinea.

A MEETING of the Surgical Society of Ireland took place on Friday evening last in the Royal College of Surgeons, when the following communications were read:—

Mr. H. Gray Croly, on "The Removal of a Hair-pin from the Female Bladder." Mr. Barton, on "A Case of Excision of the Hip."

WE learn that Dr. E. M. Grace, the well-known cricketer, is a candidate for the coronership of West Gloucestershire, rendered vacant by the resignation of Dr. W. S. Garsford, who has held the office for nearly twenty years.

A VACANCY in the surgical staff of University College Hospital has been created by the resignation of Sir Henry Thompson, F.R.C.S. This early retirement from the public duties of the hospital is due to the pressure of private professional work.

It appears to be a settled question that the Metropolitan Asylums Board will proceed to the erection of a fever hospital at Hampstead, notwithstanding the protests of the inhabitants. At a meeting on Saturday the following resolution was carried:—

"That having regard to the letter of the Local Government Board, dated 18th of December, 1874, the Hampstead Committee be and are hereby now requested to proceed under the reference to them of the 24th of October last, to obtain plans for the construction of the buildings at Hampstead."

AT the Rugby weekly Board of Health meeting on Saturday, Dr. Wilson, medical officer of health, reported that the town was now free from small-pox, and he hoped that the public alarm which had naturally arisen in consequence of the outbreak would now subside, and that the reputation for healthiness which the town had hitherto enjoyed would be restored.

SUNDAY was held as a day of thanksgiving by the inhabitants of Over Darwen, in consequence of the complete purgation of fever from the town. During the recent epidemic no less than 2000 persons were attacked, more than 100 of whom died. Over Darwen has, therefore, cause for rejoicing.

Literature.

THE PERIOD OF INFECTION IN EPIDEMIC DISEASE. (a)

THIS is a very valuable pamphlet. The first object in collecting the observations was to define with all possible accuracy the interval between the reception of infection

(a) "The Period of Infection in Epidemic Disease." By William Squire, M.D. London: Churchill. 1874. Pp. 80.

and the appearance of symptoms in some of the more common epidemic diseases. This interval is the period of incubation. The shortness of the incubation of scarlatina is a ready means of distinguishing that disease from measles. The old quarantine, or six weeks' isolation, says our author, considered necessary for those who had suffered from an infectious illness, is a near approximation to truth, three weeks being allowed for the course of the disease, and three weeks for the precautions after convalescence. Small-pox, vaccinia, measles, rubeola, mumps, varicella, typhus, and typhoid fever represent diseases having a long incubation period; relapsing fever, scarlet fever, diphtheria, plague, cholera, yellow fever, diarrhoea, influenza, dengue, erysipelas, and whooping-cough have short incubation. "A long incubation period is generally followed by a very definite illness, terminating in a crisis, and, excepting debility, with sequelæ neither very prolonged nor very definite, the infection ceasing at a comparatively early period of convalescence. A short incubation period commences a sudden morbid disturbance, having either a long or a short process, very liable to relapse, and to prolonged or definite sequelæ, infection persisting far into convalescence. It follows that infection is spread most at the end of these diseases, with a short incubation, generally from impatience of their lingering effects, and as the earlier, or even the earliest part of these, from disregard of their premonitory symptoms." In 48 cases of measles the incubation period was found to be about a fortnight. Small-pox has been taken *in utero*, and the rash of measles three weeks after birth. The youngest infants often go through scarlet fever favourably, and whooping-cough may occur a fortnight after birth. Small-pox incubates about fourteen days, when infectiously acquired; seven or eight days when inoculated.

AN EXPERIMENTAL INQUIRY INTO THE NUTRITION OF ANIMAL TISSUES. (a)

THE object of this excellent memoir is to give a description and explanatory statements of the investigation the author has undertaken into the phenomena of the nutrition of animal tissues, those relating more particularly to the nutrition of muscles and lungs in health and in cases of phthisis. Professor Graham noticed that, as a rule, substances possessed of the property of crystallising (such as common salt or sugar), yielded solutions much more diffusible than those of substances which were not possessed of the power of crystallising, such as gelatine; hence he classed substances into crystalloids and colloids. Kühne, of Heidelberg, has obtained a jelly he has called *myosine*, from muscular tissue. Bone may be considered as consisting originally of a jelly of a colloid matter and water. From his experiments, Dr. Marcet comes to the conclusion that muscle is not a solid colloid body, although formed of colloid molecules, but is permeated in every direction through its mass by a multitude of minute channels charged with the material destined to its nutrition, to which the albumen belonged. The constituents of the solid material are bound together in every molecule by a force similar to that which connects gelatine and water in a jelly. Muscle contains nearly 25 per 1,000 of its weight of potash and magnesia salts. Its tissue is constantly undergoing change. Very soon after it attains its highest stage of development, or state of maturity, it dies, and is decomposed into crystalloids. All tissues, says Dr. Marcet, are formed of three different classes of substances; those which constitute the ripe tissue, or the portion of the tissue insoluble in water; next, those constituting the nutritive material of the tissue, which are soluble in water and colloid; and finally, those of which the effete material is formed; these are soluble in water, crystalloid, and diffusible.

(a) "An Experimental Inquiry into the Nutrition of Animal Tissues." By William Marcet, M.D., F.R.S. London: Longmans. 1874. Pp. 52.

TOBACCO AND ITS EFFECTS. (a)

THIS is a well-written and convincing pamphlet, and should be read by all males, since, as the author says truly, three-fourths of that sex partake of tobacco in some shape or other. "Discussions," says Dr. M'Carthy, "have arisen from time to time in medical circles regarding the probable effects, present and ultimate, of tobacco on the public health; and recently, one medical gentleman in particular, Dr. Drysdale, of London, has with much force condemned its use, accusing it of being the direct cause of certain ailments, and believing that a certain want of stamina may result from its already too extensive use, and maintaining that thus to admit it into the list of luxuries is a violation of the laws of hygiene." Generally, the first indulgence in tobacco sickens, and tobacco is a narcotico-acrid poison. As a rule, narcotics, such as opium and tobacco, have, in small quantity, stimulating qualities. The nicotine contained in the smoke drawn through pipes and cigars is taken into the circulation through the mucous membrane of the mouth and tongue, and any inhaled by the lungs. When the young smoker smokes a second time, the semi-deprived nervous monitors cannot as readily perceive the deleterious properties of the tobacco; they are, therefore, tardy in admonishing the system; so that, on account of the additional depravity superadded after each successive smoke taken, the smoker may in this manner go on gradually and habitually increasing the tobacco, both as regards quantity and strength, and actually must do so if he wishes to feel at all times equal gratification in the act. It is in youth especially that tobacco-smoking is detrimental. In the Strasbourg tobacco factories the workmen employed in the chambers where fermentation goes on are said to lose their memory in a marked degree, and their complexions are sallow. Such pamphlets are much needed.

UNE LEÇON ORALE DE CLINIQUE CHIRURGICALE DONNÉE A L'HÔPITAL SAINT-PIERRE DE BRUXELLES. (b)

IN this pamphlet Dr. Guillery speaks of the treatment of fractures of the thigh, that is, of the body and neck of the femur. In all other bones but the femur it is easy to keep the bones in correct position whilst uniting; it is always difficult in fractures of the femur. The thigh-bone, the longest in the skeleton, furnishes for its muscular apparatus an arm of a lever of greater length and more powerfully acted on than anywhere else. The difficulty increases the further up the fracture is. Continuous extension, one of the chief means of treating this fracture, does not date from yesterday, for Hippocrates and Galen invented it. Extension permits us to combat displacements of the bone in the path of its length. With regard to displacements in the direction of the thickness of the limb, we employ sand-bags and bandages. The apparatus made use of by Dr. Guillery in such fractures consists of a rectangular box, the distal end of which has a slit in it, over which a cord passes to a pulley attached to the post of the bed, to which cord a weight is attached. The edge of the box prevents the rotation outward of the foot and thigh-bone. A little zinc bowl is employed as a weight, and this can be filled with shot until the weight desired is attained. The bandage is applied from the pelvis down to the knee. Old persons with fracture of the neck of the femur are kept sitting in bed. The weight used for extension is generally 600 or 700 grammes, and no counter-extension is used.

AUTOBIOGRAPHY OF A. B. GRANVILLE,
M.D., F.R.S. (a)

DR. GRANVILLE, of late years well known to the profession as the enthusiastic advocate of the waters of Kissingen, and who practised many years in London, was born an Italian, and only after a series of extraordinary adventures became naturalised in England, and rose to be a Court physician. He has written for us his own life, and for variety of adventure, as well as other merits, these two volumes can scarcely fail to interest our readers. He was mixed up in most of the political movements which resulted in the freedom of Italy under her present king. When he had graduated at Pavia he escaped the conscription by joining a travelling party of comedians. He then bade farewell to Italy, suffered shipwreck, visited Greece, the Holy Land, Turkey, Spain, Portugal, Russia, Germany, France, &c. In Turkey he became second physician to the Sultan's fleet, where, however, he only served a few months. After several years' travelling, he obtained an appointment as assistant-surgeon on a British man-of-war. He became full surgeon in our navy, but in 1813 he left that employment and settled in London. He was employed for some time in translating documents for the Foreign Office, and he was entrusted with other commissions. His later life is better known to the profession. Obviously the record of a life so full of unexpected vicissitudes is agreeable reading, besides which, Dr. Granville was possessed of great powers of mind, and these were set off by many accomplishments. Perhaps it is these which give here and there a touch of vanity to the narrative; but as his political prophecies proved true, we must credit him with a good deal of sagacity. The account of the last years of his life is from the pen of his youngest daughter, and concludes two very interesting volumes.

SYMPTOMS ARISING FROM OVER-APPLICATION
IN SCHOOLS AND WORKSHOPS; SHORT-
SIGHT; HYGIENE OF SCHOOLS; COLOURED
LIGHT; CORRECTIVE GLASSES; EMPLOY-
MENT OF HOT WATER; TREATMENT OF
SHORT-SIGHT IN CHILDREN BY ATROPINE
AND REST.

(Translated from the *Journal de Médecine* for December,
by FRANCIS M. LUTHEB, M.D., Cappelouin.)

GREAT progress is daily made in the study of the lesions of the organ of vision. The remedy doubtless naturally locates itself alongside the evil, for the progress of civilisation contributes powerfully to the production of disease of this organ. The very rapid augmentation of disturbance of refraction, and especially of myopia, in young people, have attracted attention to the hygiene of schools; the symptoms observed in a great number of working people pursuing certain trades; and those to which a crowd of professionals who are compelled to follow their avocation uninterruptedly in a broad glare of light, are subject, come daily under the notice of the practitioner. Accordingly we have collected the most certain information on the subject, and deduced practical rules for our readers' guidance.

Much has been written on this subject. Among the most recent works we must notice that of M. Gayat ("Ocular Hygiene in the Schools and City of Lyons") and that of M. Grand ("Hygiene of Sight in Work which demands Close Application of the Eye"). We have borrowed from

(a) "Autobiography of A. B. Granville, M.D., F.R.S., being Eighty-eight Years of the Life of a Physician." Edited by Paulina B. Granville. In 2 vols. London: H. S. King and Co. 1874.

them most of the following considerations. The latter author dwells upon the fact that for the examination of small objects the eyes have to be approximated, an effort of accommodation, convergence of the eyes is requisite, and if the object is on a flat table, a bent posture of the head and body. Hence result ocular congestion, a tendency to inflammation, premature presbyopia, paralysis of accommodation. Lastly, among the gravest consequences of those efforts must be signalled myopia. Erisman, in Russia, has demonstrated by statistics of schools formidable and conclusive results; he found 34 per cent short-sighted. Boarding schools suffer more from it, for in the German schools where the pupils are extern the percentage he found to be but 24, and in a similar establishment he found the figures to be—pensionnaires labouring under myopia, 43 per cent.; externs, ditto, 35 per cent.

It is during the period of growth, from 12 to 18 years, that this result is produced; under the influence of augmented pressure the eye is elongated, the fundus yielding to the distension.

The influence of the luminous rays vary with their colour. Red light, for example, with its calorific rays, exerts an unfavourable influence on the eye; so also the violet rays are prejudicial. Boehm has shown that the blue rays are the least injurious.

Experience has caused blue glasses to be employed in order to diminish the irritation caused by light, and Boehm uses them not only with this object but as a therapeutic means. Moreover, the impression of the blue rays, as well as being the easiest tolerated, is likewise the most enduring upon the retina.

Other authors agree with M. Dobrowski in thinking that blue glasses have the inconvenience of not weakening sufficiently the red and violet rays. The employment of smoked glasses would be preferable.

M. Grand thinks that for inflamed eyes the employment of smoked glasses would be preferable; that during work requiring close application one must avoid diminishing too much the intensity of the light. If it is too dazzling you will use smoked glasses; if it is too much charged with yellow or red rays, such as gas, or mineral oil, blue, or greenish-blue glasses, will be employed with benefit.

One should avoid too intense a light, and likewise gazing fixedly at objects that impair the sensibility of the retina.

Insufficient illumination is as prejudicial as an excess of light; it leads to a diminution of visual perception. Certain circumstances, such as want of movement, want of variety in luminous sensations, and dwelling in dark places are very hurtful.

M. Grand lays down some hygienic rules.

For the worker the light should come as much as possible from the left side, that is to say, from the side towards which one turns in working.

Day-light is the best; but one should avoid direct sunlight; that of reflecting mirrors should also be avoided. The aspect should be northern, and the light should come a little from above. Light coming from the right, too high or too low—all those defective conditions cause school children particularly to take all sorts of awkward positions.

White walls should be avoided, highly varnished tables, and in workshops, shining articles like silk should be protected from the sun's rays.

Artificial light is always bad, on account of the heat and the exhalation of carbonic acid. The best is that of lamps fed with vegetable oil and furnished with a glass shade. Gas is bad, because of its heat, brilliancy, and mobility; the light of mineral oils is too hot; that of candles insufficient and flickering. An oil lamp should be covered with an opaque moderateur; the eye of the workman should avoid the light coming to him directly or diffused through the room. The moderateur should be white, green, or grey.

Working after meals is injurious. Inclination of the head should be avoided. One should write on an inclined plane; and in schools it would be good to supply a movable back-board for the children.

Application of the eye must always be interrupted from

time to time. Reading in bed, lying down, is to be deprecated from every point of view.

M. Grand recommends, when the eyes are fatigued by constant work, lotions of cold water, and, if the eyes are subject to catarrhal inflammation, of tepid water. As regards this our advice is totally different.

We believe that washing with cold water, and the employment of iced water is bad. We see well-known ophthalmologists, M. Galezowski, for instance, recommending hot water for the slighter maladies of the eye. We have always seen washing with hot water, *very hot water*, after continuous application, render very great services to the weary eye. We beg of our readers to urge this method on their patients.

If the eyes are fatigued by bad artificial illumination, blue, or slightly smoked glasses, will be useful, and in order to avoid the lateral rays they should be large and round.

If the irritation of the eyes persists all work must be abandoned, and an examination made to see if there be any disturbance of refraction of power of accommodation or of the mobility of the eyes.

Presbyopia supervenes earlier with those who are constantly at work than with other individuals, and as soon as it does, convex glasses should be at once resorted to, without which the muscle of accommodation would be fatigued to no purpose. At first they should be used for working in the evening, after the fatigue of the day; but a long-sighted person should only use spectacles for looking at near objects, not at far ones.

Work requiring close application, favour the development of myopia precisely in proportion as the conditions of illumination are bad.

If the action of those causes continues the myopia continues to increase until vision is lost.

A slight degree of myopia may be favourable to close work, but, as a general rule, work requiring close application, by the derangement of circulation that it inevitably induces in the eye, is much more injurious to the myopic, and is the great cause of the development of myopia and its complications. Young people should be examined, and, *if they are myopic, hindered from undertaking tedious studies and all professions demanding close application of the eye.*

For myopic persons especially, the precautions above indicated should be observed. More light is required; the eyes must be rested; exercise in the fresh air must be taken; mustard foot-baths from time to time. In the sunshine slightly smoked glasses are advantageous.

As to corrective glasses, they have the advantage of permitting the object to be studied to be held at a distance, but they diminish the size of the images; the individual approximates the eyes, and makes efforts of accommodation, particularly if his sharpness of vision is impaired. The short-sighted person ought then only to wear glasses for looking at near objects when there is no complication or diminution of perception.

The hypermetropic, by constant efforts of accommodation, succeed in seeing near objects. Then, when constant work has fatigued the eye, accommodative asthenopia supervenes, pain is produced, and vision cannot be accomplished. The indication for those who have to work continuously is to wear convex glasses. By-the-way, there is a popular prejudice that one ought not to wear strong glasses. That is a mistake. Whatever best relieves the eye is the one to choose. Glasses have, moreover, the advantage of diminishing the tendency to convergent strabismus.

Certain circumstances, astigmatism, lesions of the cornea, paralysis of the muscles supply special indications.

The employment of magnifying glasses and microscopes does not cause special accidents to the eye. The inconvenience of illumination and continuous application are the same as for other kinds of work. Still, prolonged microscopic observations leave a contraction of the muscle of accommodation leading to transient myopia, which finally becomes permanent and progressive. Frequent repose and the alternate use of the two eyes is recommended.

Dr. Guyton has studied most carefully the derangements

of refraction of the eyes in schools, and myopia in particular, which is of such frequent occurrence, most frequent, as Malakoff shows, in the higher classes. In girls' schools it is more frequent than in boys'.

It has been asked, if there is no therapeutic means of combating the development of those lesions, and the recent work of M. Schiess-Gemuseur, of Bâle ("*Annales d'Oculistique*"), makes one hope for good results. He there gives an account of the results obtained in treating young persons suffering from short-sight by rest and atropine.

M. Dobrowski had already noted the following fact: In myopia, especially in the beginning of it, part is referable to a cramp of the muscle of accommodation, which is accompanied by injection of the eyes, by catarrh, and very often by winking. The ophthalmoscope shows that the fundus of the eye undergoes some change, and many reasons permit one to suppose that those results are the result of the continual tension of the muscle of accommodation.

Consequently the indication was to suppress this cramp of the muscle of accommodation, and atropine (*a*) does this. The favourable results obtained by the employment of this substance whenever we wish to diminish the tension of the globe of the eye are well known.

Nothing but rest of the eye in very pronounced myopia can much diminish the myopia. But the instillation of atropine caused the myopia to disappear in a fifth of the children under observation, diminished it much with others, and remained without any effect in some. The author was led to conclude that the employment of atropine can ameliorate definitively a great many cases of myopia, and in some slight cases cause it to disappear entirely. In such the benefit has lasted long after the treatment has been discontinued.

The treatment consists simply in the instillation, once or twice a day, of one drop of solution of atropine of strength 1-120, the use of blue spectacles, and total cessation from all work requiring close application of the eye; the treatment was only continued for three or four weeks.

This rapid *résumé* shows how the physician can interfere with benefit to hinder the development of the diseases of the eye referred to, and even to effect their cure. We must cease to consider myopia (*b*) as a congenital defect and an inevitable evil. We must also advise those suffering from defective vision not to rest satisfied with going to a spectacle-maker, since we have much to tell them.

COMMUNICABILITY OF SCARLATINA AND MALIGNANT SORE-THROAT BY WATER.

WE publish to-day, from the pen of Dr. Routh, an interesting and valuable communication upon an epidemic of scarlatinoid disease observed by him, and in it he raises a very important question, upon which our readers will bestow well-deserved attention. The epidemic had an immediate relation to the occurrence of a peculiar foulness in the cisterns of the house.

The peculiar disagreeable flavour and smell of the water was only observed during the months of August and September. This is the period when, perhaps, decomposition is most rapid, at least in London, and no doubt it was only more evident now, but perhaps had existed many months previously; but here a remarkable coincidence was observed. Only one of the monitors (*i.e.*, girls which are placed in authority over the others) suffered from the epi-

(a) Atropine is said to be injurious in glaucoma—a disease produced by intra-ocular tension. More likely it is the glare of the ophthalmoscope.

(b) The extract of Calabar bean, when first introduced into France, was asserted to cure myopia. Perhaps it may be suited for a different stage, since it affects the pupil differently from atropine.

dem, and she was a water-drinker. The other five were allowed beer, in one case wine, and therefore did not partake of the water, except when boiled to make tea or coffee. Five of the matrons (of which there are also six) escaped in the same way, but this sixth one was a total abstainer, and therefore a water-drinker, and she was the first seized, soon after her appointment, and it was said, as before remarked, that she had brought the disease in the Home. Whether this was true or not, there is a remarkable coincidence to be observed between the water-drinkers and the cases obnoxious to the epidemic.

A CENSURE FOR PRESENCE OF MIND.

WE publish in our present issue two cases of intestinal obstruction treated by catheterization *per rectum* which the author, Dr. Colahan, of Galway, has desired to submit to the judgment of his brethren. We invite their criticism upon the cases, because, curious as the statement may be, they have been made the subject of a vote of censure upon Dr. Colahan by his Board of Guardians, and of a subsequent excited debate, upon which the censure was reversed.

The proceedings of the guardians are too extended to permit their transference to our columns. It is sufficient to say that Dr. Cleland, the colleague of Dr. Colahan, thought it right to pen a note in the prescription-book, in which he expressed his opinion that "it is highly improper to use for such purposes a tube intended to be put down patient's throats," and that note was brought under the notice of the Board by Dr. Brodie, the Local Government Board Inspector.

Without making any inquiry, or rather, we should say, in the teeth of Dr. Colahan's explanation that the stomach tube was used in an emergency, and to save life, there being no rectum tube, the guardians voted a censure on Dr. Colahan. This course compelled Dr. Colahan to enter into a full justification of himself, which he did at the following meeting of the guardians, giving in his letter, the professional authority and approval under which he had acted, and the guardians, seeing that they had been induced to commit an injustice, unanimously resolved that—

"The Board having heard Dr. Colahan's explanation, withdraw any censure that may have been implied in the letter of the Secretary to him, arising from the proceedings at last Board meeting, in reference to the report of the apothecary upon Dr. Cleland's observations about the use of the stomach-pump in the workhouse hospital. And that Dr. Colahan's letter be inserted on the minutes."

As to the position occupied by the guardians in the matter, we have nothing to say but that, having been hastily induced to pursue an unjustifiable proceeding they adopted the only course open to them as gentlemen, and, at the earliest opportunity, made the necessary *amende*.

The figure cut by the medical men who lead the attack upon Dr. Colahan is entirely different, and it strikes as being creditable neither to themselves nor their profession. They had the means of satisfying themselves of the urgency of the cases before they undertook to censure Dr. Colahan, and their professional experience ought to have made them aware that, under the circum-

stances, such a censure was entirely undeserved. It is humiliating to the profession to observe that its own members, whose professional knowledge and personal acquaintance with the facts ought to have called upon them to testify that Dr. Colahan acted with propriety, stepped to the front with one accord to throw the stone and follow up the blow aimed at him.

DR. R. V. FLETCHER, now Resident Medical Superintendent of the District Lunatic Asylum, Waterford, has been appointed Resident Medical Superintendent of the District Lunatic Asylum for the counties of Galway and Roscommon at Ballinasloe.

THE Dublin Hospital Sunday collection has realised over £3000, a sum which, though small for such a city as Dublin, appears large when the circumstances are considered. Not only did the Roman Catholic community, which constitutes a large numerical majority of the population, stand aloof, but a few of the unsectarian hospitals also refused to give any aid or to throw in their lot with their neighbours. In doing so we fancy they committed a cardinal mistake, and have deprived themselves of a share in the distribution without at all increasing their chances of private donations thereby. The money will be distributed at once, upon what principle we know not. We hope that a really equitable method of assessment has been hit upon, such as will ensure that the money will really reach the deserving poor.

THE election of a Professor of Midwifery in the Irish College of Surgeons in the room of Dr. Sawyer, resigned, will take place on the 14th inst. The Fellows of the College have, as is usual, been summoned to witness the election, and the choice will be made according to the charter arrangements by seven of the Council, who will be chosen by lot. The candidates, as far as we are aware, are Dr. John Cronyn, who formerly acted temporarily as Professor during the illness of Dr. Sawyer; Dr. William Roe, Assistant Obstetric Physician to the Coombe Hospital; Dr. Thomas More Madden, Assistant-Physician to the Rotundo; Dr. Rutherford Kirkpatrick, an Examiner in Midwifery in the College; and Dr. Arthur Hill Ringland, Assistant-Physician to the Coombe. The emoluments of the chair consist of pupil fees amounting to about £150 a year.

Correspondence.

FRACTURE OF SKULL WITH HERNIA CEREBRI.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I read with considerable interest in the last number of your valuable journal a case of "Fracture of the Skull followed by Hernia Cerebri," by Dr. Adamson, and am induced through it to bring to mind an almost similar case treated by myself about two years since, when medical officer of the Coolmountain dispensary district.

The case was that of a strong, hearty boy, about 12 years of age, who sustained (by what means never came to light) an extensive, open, compound comminuted fracture of the right frontal and parietal bones of about an inch and a half in circumference. He was found lying in a field close to his

house in a pool of blood, and although conscious all through his illness, he could not account as to how he came by the accident, if such it was.

The membranes of the brain were ruptured, and the brain substance protruded externally.

It being night when I saw him, and the boy being frightened and restless, and there being no urgent symptoms, I merely applied a little water dressing, and directed perfect quiet, &c.

Next morning he was nothing worse, and the portion of brain which I saw the previous night beginning to come away, I perceived beneath it the glistening surface of a piece of bone, which, on examination, finding detached, I removed immediately.

The following day I detected two other portions of bone, which I removed. Suppuration was now setting in, and light poultices of linseed meal were ordered, with carbolic lotion, nourishing drinks, head shaved, and cold application applied, with small doses of calomel given at intervals, which was continued afterwards until he was slightly salivated, and this kept up for a short time.

As the suppurated brain substance came away, I detected almost daily, pieces of bone, both frontal and parietal (as well as I remember), thirteen in all, which were at once removed. It will be observed that in the first instance the bones were driven deep into the anterior lobe of the cerebrum.

All went on well, with, of course, variations of pulse, temperature, &c., notes of which were carefully taken daily, but subsequently lost.

The vacuum left in wound began to fill in, and wound itself now began to look healthy. Simple dressing was ordered, with a pad and bandage, lightly applied.

On my daily visits the edges of wound were noticed to close more and more. Subsequently the brain (beginning to adapt itself to its diminished and irregular space) forced itself, together with the remaining gangrenous-looking and unhealthy edges of membranes, through wound, and had to be sliced off on two successive occasions, to prevent its further protrusion and enable wound to heal.

Simple dressing with pad and gentle pressure was still continued, until, at the end of three months, everything going on well, wound closed completely, and to my entire satisfaction.

I now gave permission to my patient to get up for a few hours daily, and, in ceasing my attendance, left him rejoicing at (to my mind) the recovery which, under Providence, I was instrumental in bringing to a successful termination, after a three months' attendance of over four miles daily.

I was doomed, however, to disappointment. My little patient, equally rejoiced at being again able to go among his companions, engaged in boisterous and wearisome exercise, which, under any circumstances, could not continue long. In a week afterwards I was sent for to see him. He was delirious; the freshly-united edges of wound opened up. He sank gradually, and in a few days was no more.

Every allowance must be made for the disadvantages under which the above is given, which must be taken as an imperfect account of treatment and other particulars, which I could not be supposed to remember after such a lapse of time. I think, however, the case is interesting, as showing—firstly, the great amount of injury which the brain in some parts (particularly the anterior cerebral lobe) can suffer almost with impunity, and also the power of self-repair possessed by it; secondly, the time this boy lived without any untoward symptom, and the probability of his ultimate recovery only for his own incautiousness.

I remain, your obedient servant,

RICHARD O'KELLY,

Resident Physician Cork Union Workhouse.

Jan. 1st, 1875.

to these infants prevents their growth; or, lastly, on account of a congenital feebleness. At the Lourcine Hospital almost all the children attacked by syphilis have succumbed rapidly; at the hospital of 'Enfants Assistés' the proportion of the deaths is still more considerable, because, at the Lourcine Hospital, there are still some mothers who can suckle their children. Death supervenes generally from diarrhoea and convulsions."

My object in calling attention to the gloomy prognosis in infantile syphilis, however treated, was to lessen the disappointment naturally felt by persons who expect the disease at once to give way to specific treatment. The circumstances of such infants are often as bad as it can be imagined; and hence the great mortality of frail creatures infected at birth with an animal poison.

I remain, Sir,

Your obedient servant,

CHARLES R. DRYSDALE, M.D.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

NOTICE TO SUBSCRIBERS.—Subscriptions in advance for 1875, at the reduced tariff of 21s. per annum, post free, are now due, and will be thankfully received by the Publishers in London, Dublin, and Edinburgh.

SCARCE NUMBERS FOR 1874.—The Publisher will be glad to purchase clean copies of May 30, June 3, November 18, or to exchange any other numbers for them.

DR. T. JONES, Manchester.—The recent deaths from chloroform inhalation point to the fact that as yet busy practitioners have not learnt to use ether so well as chloroform in this country. Ere long it is to be hoped public medical opinion will enforce attention to the fact that ether is infinitely less dangerous to life than chloroform, and that with a well-constructed apparatus, admitting of a large evaporating surface, and plenty of air, the administration of ether is not much more difficult than that of its more dangerous allies—chloroform and methylene.

MR. COOPER will find the subject noticed in our columns of May 13th, 1874.

MR. J. M. will find the matter about which he writes in another column of the present number.

AN INQUIRER.—You will find Bellamy's "Handbook of Anatomical Plates" the best work for your purpose.

MR. J. C. D.—Received too late for the present number. Proof will be sent you.

INDIAN CANDIDATE.—The next competitive examination for appointments in the Indian Medical Service is definitely fixed for the 15th proximo. Our advertising columns will supply full information.

COMMUNICATIONS, Enclosures, &c., have been received from—Dr. John Harley, London. Mr. Teevan, London. Dr. Stead, Manchester. Mr. McLean, Norwood. Dr. Lory Marsh, the Medical Club. Mr. Jebb, Metropolitan Asylums Board. Dr. Carey, Taunton. Dr. Bothwell, Worcester. The Registrar, Royal College of Physicians of London. Mr. Norton, London. Mr. Webster, Bedland, Bristol. Dr. E. Williams, Colchester. Dr. Lombe Atthill, Dublin. Mr. Gray, London. Mr. Heathcote, London. Mr. Sloane, Forest Row. Mr. Lennox Brown, London. Dr. Purdon, North Riding Asylum. Dr. Clark, Staines. Dr. Macaw, Bushmills. Dr. Spence, Lettirkenny. Dr. Fry, Moate. Dr. Sheehan, Buttevant. Dr. Barber, Coleraine. Dr. McCaul, Londonderry, &c., &c.

VACANCIES.

Metropolitan Asylums District. Medical Superintendent for the proposed temporary Asylum for Imbecile Children. Salary, £100 per annum, with furnished house, &c. Forms of application to be obtained of W. F. Jebb, Esq., 27 Norfolk Street, London, W.C. (See Advt.)
Beckett Hospital. House Surgeon. Salary, £140 per annum, with rooms, &c. Applications to be addressed to the Secretary, at Barnsley.
Scarborough Union. Medical Officer. Salary, £30 per annum, with fees extra. Candidates must address the Clerk to the Guardians.
Lettirkenny Dispensary. Medical Officer. Applicants must send in their testimonials at once, addressed to the Hon. Sec. (See Advt.)

THE PROGNOSIS OF INFANTILE SYPHILIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

In support of what I said regarding the prognosis in infantile syphilis, however treated, being very gloomy, may I quote the following from Dr. Armand Després' "Traité de la Syphilis," 1873, p. 376:—

"The great number of syphilitic infants die, whether because the treatment is not given to them, or because the mother who nurses them is a bad nurse; or, again, because the treatment

Royal Free Hospital, London. Junior House Surgeon. Board and residence in the Hospital. Mr. Blyth, the Secretary, will furnish full particulars. (See Advt.)

St. Mary's Hospital, Paddington. Resident Registrar. Salary, £100 per annum, with board, &c. Applicants must address the Secretary.

Poplar Union. Medical Officer for the South District of the Union. Salary, £170, inclusive of all fees. Application to the Clerk to the Guardians at the Board Offices, Poplar, E.

Derbyshire General Infirmary. Assistant House Surgeon. Board and residence, but no salary. Address the Secretary.

Birmingham General Dispensary. Resident Surgeon. Salary commencing at £180. Application to the Secretary.

Bridgnorth Infirmary. House Surgeon. Salary commencing at £120. Application to the Hon. Sec.

Alderbury Union. Medical Officer for the Workhouse at Britford and for No. 4 District. Salary, for the joint offices, £100, with fees extra. Address, Mr. T. Jesse, Salisbury.

APPOINTMENTS.

ADAMS, M. A., F.R.C.S.E., Public Analyst for the County of Kent.

ALEXANDER, W., M.D., C.M., Medical Officer to the Workhouse, Brownlow Hill, Liverpool.

ANTHONY, H., M.R.C.S.E., Sanitary Officer for the Dugarvan Urban Sanitary District.

BRANFORD, H. S., M.B., a House Surgeon to Guy's Hospital.

CARSON, Dr. J. C. L., Consulting Sanitary Officer for the Borough of Coleraine, Ireland.

COLLINGWOOD, J. E., L.R.C.P.Ed. Medical Officer for the Burton-Coggles District of the Grantham Union.

CREAN, C. E., L.K.Q.C.P.I., Superintendent Medical Officer of Health and a Sanitary Officer for the Clarendon Rural Sanitary District.

DAVIES, J., L.R.C.P.Ed., M.R.C.S.E., Medical Officer for No. 2 District of the Worcester Union.

EVANS, C., F.R.C.S., Medical Officer to the Workhouse, Bakewell Union.

FALKNER, F. J., M.B., Superintendent Medical Officer of Health for the Naze Rural Sanitary District.

FLETCHER, R. V., L.R.C.P.Ed., Resident Medical Superintendent of the Ballinacloe District Lunatic Asylum.

GILLESPIE, J. M., M.D., L.R.C.S.Ed., Medical Officer of Health for the Accrington Urban Sanitary District.

GRADY, W. G., M.D., M.R.C.S.E., L.R.C.S.I., Medical Officer for the No. 8 District of the Parish of St. Pancras.

HUME, G. H., M.D., L.R.C.S.Ed., Lecturer on Anatomy at the University of Durham College of Medicine, Newcastle-on-Tyne.

JONES, H. M., M.D., F.R.C.S.I., F.R.C.S.Ed., Ordinary Physician to the Cork Fever Hospital and House of Recovery.

KELLY, D., M.R.C.S.E., Superintendent Medical Officer of Health for the Mullingar Rural Sanitary District.

LANGAN, F., L.R.C.S.I., L.M., L.K.Q.C.P.I., Medical Officer, &c., for the Kingscourt Dispensary District of the Baillieborough Union.

M'DOWELL, C. W., M.D., Sanitary Officer for the Carlow Urban Sanitary District.

M'DOWELL, F. V., L.R.C.S.I., Superintendent Medical Officer of Health for the Carlow Urban Sanitary District.

MORRIS, S., L.R.C.P.L., M.R.C.S.E., House Surgeon to the General Infirmary, Gloucester.

O'NEILL, P. L., L.R.C.P.Ed., Superintendent Medical Officer of Health for the Athy Rural Sanitary District.

PAGE, F., M.D., M.R.C.S.E., Lecturer on Medical Jurisprudence at the University of Durham College of Medicine, Newcastle-on-Tyne.

PAUL, F. T., L.R.C.P.L., a House Physician to Guy's Hospital.

PROCTOR, W. B., F.R.C.S.E., L.M., Medical Officer to the Workhouse, Bradford Union, Yorkshire.

REID, J. S., M.D., Superintendent Medical Officer of Health for the Belfast Rural Sanitary District.

RUSSELL, J., L.K.Q.C.P.I., Superintendent Medical Officer of Health and a Sanitary Officer for the Thurles Rural Sanitary District.

STERLING, M., L.R.C.S.I., Superintendent Medical Officer of Health and a Sanitary Officer for the Thomastown Rural Sanitary District.

STEWART, W. M.D., Sanitary Officer for the Portadown Urban Sanitary District.

Marriages.

CHON-VENABLE.—On the 6th inst., at Christ Church, Broudesbury, Middlesex, James Edward Schon, M.R.C.S., to Ellen Emma, eldest daughter of the late George Henry Venables, of Warley Lodge, Broudesbury.

Deaths.

BELL.—On the 30th Dec., Peter MacDonald Bell, M.D., of Accrington, aged 33.

BROWN.—On the 25th Dec., S. Brown, L.R.C.P.Ed., of Fletching, Sussex.

CLARKE.—On the 1st Jan., F. Clarke, M.R.C.S.E., of Percy Road, Shepherd's Bush, aged 71.

HANDS.—On the 6th Jan., suddenly, at his residence, Kirkdale Lodge, Sydenham, Benjamin Hands, F.R.C.S., &c., late of Hornsey, Middlesex, aged 73.

HARTLAND.—On the 24th Dec., Wm. Bryan Hartland, L.S.A.L., of Torquay, aged 68.

PHILLIPS.—On the 5th Jan., Edward Phillips, M.D., of Harley Street, London, aged 51.

POCOCK.—On the 1st Jan., G. E. Pocock, M.R.C.S.E., of Cannon Place, Brighton, aged 58.

LAYTOR.—On the 3rd Jan., John Corney Slaytor, L.S.A.L., of Newton Abbott.

STEDMAN.—On the 30th Dec., at Sharnbrook Grange, Bedford, Robert Savignac Stedman, M.R.C.S.E., in his 48th year.

WINTER.—On the 31st Dec., Thos. Bradbury Winter, M.R.C.S.E., of Brighton, aged 77.

Established 1848.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S., &c. (KING'S COLL.), and Author of VIA MEDICA.

Has always upon his books a large number of desirable Investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

PRACTICES AND PARTNERSHIPS NOW OPEN for Negotiation (in addition to those advertised in Dr. Langley's List, which is sent post free on application).

Z 36. WEST-END NUCLEUS. An effective introduction can be given to a good connection in Bayswater, realising upwards of £300 a year. The residence is well situate at a corner, and is held on beneficial lease at £63 a year.

Z 84. WEST-END. In consequence of illness it is desired to make an immediate arrangement for the TRANSFER of a PRACTICE, the average receipts from which have been £600 a year. Midwifery £1 1s. to £5 5s. The residence is well situate, contains thirteen rooms. Rent £70. Premium £250 to an immediate purchaser.

Z 76. FIRST-CLASS PRACTICE in a pleasant provincial town, about 70 miles from London, with direct rail. The practice is old established, and the whole connection transferable to a suitable gentleman. The actual receipts average £800 a year. Population about 3,000; only two opponents. Midwifery fees from £1 1s. to £5 5s. All appointments declined. The residence is convenient and well situate, containing twelve rooms, with good stabling, detached surgery, &c.; held on lease. Rent £70.

Z 83. PRACTICE or PARTNERSHIP.—The SUCCESSION to a FIRST-CLASS PRACTICE in a good market town within easy access of London can be secured by an effective introduction by Partnership or otherwise. Receipts upwards of £1000 a year. Midwifery fees £1 1s. to £10 10s. The house contains ten rooms, with detached offices, garden, conservatory, stabling, &c. The premium required will depend upon the length of introduction agreed upon.

Z 81. Within 15 miles of London, a JUNIOR PARTNERSHIP in a good GENERAL PRACTICE, in a suburban locality. A fourth share for disposal, with succession to further share hereafter upon equitable terms. The receipts are £1,350 a year, and there is great scope for increase. There is little dispensing. The Junior could at first reside at the branch surgery. Premium, £675, part of which may be left on security, and paid by instalments.

Z 80. In a prosperous and picturesque district, an OLD-ESTABLISHED PRACTICE, yielding in actual receipts £1,100 a year. Age the cause of retirement. Appointments bring in £62 a year. The house is well situate, contains 10 rooms, with detached surgery, offices, stabling, and large garden. Rent 40 guineas. The working expenses amount in all to about £300 a year. An effective introduction by *quasi* partnership or otherwise as long as may be desired. Part of the premium may be paid by instalments. The whole connection is safely transferable to a suitable gentleman, and there is great scope for increase as there is a population of about 15,000 inhabitants.

LOCUM TENENS WANTED.—For fully-qualified gentlemen of experience and unexceptionable character, Dr. Langley can find constant employment on liberal terms. Apply PERSONALLY at 50 Lincoln's Inn Fields, as above.

CERTAIN NERVOUS AFFECTIONS OF THE THROAT. (a)

By CLINTON WAGNER, M.D.,

Physician to the New York Throat Hospital; late Assistant in Dr. Prosser James's Clinic at the London Throat Hospital.

LARYNGEAL NEURALGIA.

NEURALGIA of the larynx is occasionally met with as a true neurosis, and independent of any other morbid process in the same individual.

The pain, which is at times intense and agonising in its character, is felt along the thyroid cartilage and anterior part of the neck, the nerves implicated being the superior and inferior laryngeal, especially the former.

There is also at times a feeling of oppression or choking, the voice is weakened and the pain increased when the least exertion of it is made.

This affection has been described by Graves, Gibbs, Handfield Jones, (b) and Türk. (c) The latter mentions that it may accompany a prolonged laryngeal catarrh or phthisis, but states also that the laryngoscope throws no light upon the pathology of the disease. The cases that have come under my own observation have all been individuals of a broken-down and unfeebled constitution, and I think it should be classed among the superficial neuralgias which Anstie describes as "excited by anæmia or mal-nutrition."

Graves relates an obstinate case which finally yielded to large doses of the carbon. ferri. Gibbs has found the bromide of ammonium in large doses very useful.

The treatment I have found most successful has been large doses of tinct. iron and quinine, and insufflations of

(a) Part of a paper read before the New York Neurological Society.

(b) "Functional Nervous Diseases."

(c) "Krankheiten des Kehlkopfes."

acid, tannic, and morphia into the larynx. Aconite liniment over the seat of pain gives temporary relief. Counter-irritation from blisters or tinct. iodine have been recommended. Hypodermic injections of morphia are also useful. Electricity in the form of the faradic current, in the few cases I have employed it, has had the effect of increasing the pain from the muscular excitation it produces, and the constant current in my hands has failed to give the relief claimed for it by others who have used it.

NEURALGIA OF LARYNX.

Mr. N., aged 28, actor, consulted me Sept., 1873, at the suggestion of Dr. Mackenzie, for a severe chronic catarrhal laryngitis of long standing. He was compelled to discharge the duties of his vocation almost without interruption, which necessarily rendered the treatment tedious. In December I discharged him cured, and in the following month he started for the South on a professional tour.

A few weeks later, while in Savannah, he was attacked with severe pain in his larynx, for which he consulted a practitioner of that city, from whom he obtained no relief. Upon his arrival in New Orleans, the pain had increased to such an intensity that he was compelled to relinquish his engagement for the time. He returned to New York, and again placed himself under my treatment.

He complained of a constant dull aching pain, extending along the sides of the thyroid cartilage, and a tickling, uneasy feeling at times at the pomum Adami. His voice was weak, and the pain was increased greatly upon any attempt being made to exert it. He was much broken down in general health, and suffered from dyspepsia. A laryngoscopic examination revealed nothing but slight congestion of the mucous membrane covering the arytenoid cartilages, and the aryepiglottic folds, by no means sufficient to account for the pain and voice weakness.

I applied locally perchlor. iron $\zeta i.$ to $\zeta i.$, and internally tinct. ferri. mur. gtt. xxx., quinine sulph. grs. v. three times daily, and occasionally the local application of liniment aconite over the seat of pain.

Under this treatment he improved, and left the city within three weeks to rejoin his company. He returned

about June 1st, greatly improved in general health, and quite free of pain.

In this case I tried the constant current, but obtained no satisfactory results from its application.

NERVOUS SORE-THROAT.

There is still a class of cases of sore-throat very frequently occurring in practice, difficult to diagnose, and still more so to treat satisfactorily.

In nervous sore-throat, dysæsthesia, or hyperæsthesia of the throat, as it has been called by different authors, the patient complains of pain or soreness involving the tonsils, pharynx, and pillars of the soft palate; it may be on both or confined to one side, increased in swallowing, with a sense of constriction, and at times of suffocation, and if a foreign body was lodged there; desire to cough, with a tickling sensation, accompanied with dryness and other disagreeable symptoms difficult to describe in words.

The general health is impaired from a prostrated or perturbed nervous system, or the patient may be afflicted with some chronic organic disease, the usual symptoms of which may be absent or masked by those I have just described; at all events, the source of all trouble is ascribed by the patient to the throat.

One would naturally expect to find serious trouble, or at least evidences of inflammatory action, with such symptoms as I have described. An examination, however, will reveal nothing sufficient to explain the cause of the patient's sufferings. The mucous membrane of the fauces may appear relaxed, and in colour pale and anæmic, the larynx normal. Instead of the dry, glazed membrane found in pharyngitis sicca, and which we would expect from the dryness complained of by the patient, there is no lack of mucous secretion visible to the eye.

The voice is weak, and any attempt at prolonged use is attended with pain, and a feeling of utter inability, for the effort.

The following case is illustrative of this form of sore-throat existing simultaneously with an organic disease:

CASE I. NERVOUS SORE-THROAT.

Mrs. —, aged about 55, a short, stout, plethoric woman, married, and the mother of a large family, consulted me early in December, 1873, at the suggestion of Dr. Marion Sims. Her symptoms were as follows: Pain in the region of the posterior columns of the palate, left side; constriction in pharynx, increased in swallowing; dryness, at times dyspnoea; but the most annoying symptom, and the one which seemed most to distress her, was that which she described as a worm, moving and constantly wriggling itself into her throat. The fauces, with the exception of a slight pharyngitis with thickening of the mucous membrane, presented the appearance of health, and a laryngoscopic examination revealed nothing but a slight venous congestion in the fossa between the base of the tongue and the epiglottis, by no means sufficient to account for her peculiar symptoms.

Applications of strong mineral astringents, with inhalations of the same, seemed to give her great relief for several days at a time. In what way they produced their effect, I am at loss to explain.

I have already stated that organic disease was sometimes present in these cases, but not always recognised in the early stages by reason of the prominence of the throat symptoms.

In this patient, fatty heart was subsequently developed, for which she has been treated by her family physician. As the cardiac symptoms became more prominent with the advance of the disease, the throat trouble subsided, and she has since declared that it gives her no further annoyance. In this case, the throat symptoms probably arose from irritation of the cardiac filaments of the pneumogastric.

It sometimes accompanies hysteria, as shown in the following—

CASE II. OF NERVOUS SORE-THROAT.

Miss —, aged about 32, tall and of spare habit, of a

delicate nervous organisation, anæmic, and very much debilitated, consulted me in February last, recommended by Dr. Hammond, under whose treatment she was for hysteria and irritation of the upper portion of the spinal cord. She complained of an almost constant pain, not of a very severe character, but sufficiently so to be annoying, increased upon swallowing or in the attempt to exert her voice. It was chiefly on the right side. There was no evidence of phthisis, but she feared the trouble arose from that cause.

Excepting a relaxed condition of the mucous membrane of the fauces, and very slight thickening of the membrane covering the arytenoid cartilages, I could discover nothing specially requiring treatment.

Local applications of iron in the form of spray and morphia upon the brush gave great relief. Anodyne and soothing inhalations were also ordered. I attribute the final cure in this case to the disappearance of the hysteric symptoms and spinal trouble under Dr. Hammond's treatment, and I have no doubt that the peculiar throat symptoms in her case arose from an irritation of the spinal accessory nerve.

I last saw her several weeks ago. Her throat appeared perfectly healthy; declared it gave her no further trouble, and local treatment was discontinued.

Of the pathology of this affection nothing is known. I think it not unlikely that that portion of the glossopharyngeal nerve which supplies the tonsils, soft palate, and pharynx is at fault. The pain is always referred to these parts, and the sense of constriction, which is so annoying, points to the implication of the muscles of the pharynx supplied by this nerve.

Treatment.—The general health must be improved; tonics, generous diet, and change of air. If the patient has lived in the damp sea air of the coast, a change to a dry mountainous region will be found beneficial, and *vice versa*.

Local applications should be of a mild soothing character. I have derived much benefit from morph. sulph. grs. viij. to ʒi., and applied by means of the brush to the parts complained of; also sprays of the same, or weak solutions of zinc or iron.

CLINICAL MEMORANDA.

Reported by JOHN W. MARTIN, M.D.,
Assistant-Surgeon Mayfield Factory Dispensary, Portland.

Hepatic Congestion—Jaundice—Recovery.

J— M—, æt. 35, officer's servant. Notes taken March 7th, 1874.

Patient stated that previous to present attack he had always been a strong, healthy man, that he has rarely been intoxicated, but that he has taken stimulants steadily for some years past, his usual allowance being two or three glasses of brandy in the day, several days a week, together with seven or eight glasses of beer daily. The symptoms presented were those of acute jaundice, the conjunctiva and skin being deeply tinged with the bile pigment, the tongue furred and loaded, anorexia, constipation, motions passed, white, hard, and clayey; pulse 84, weak and compressible; general lassitude; urine scanty, high coloured, but not presenting the characters of urine usually observed in cases of icterus.

The attack had commenced March 5th, with rigors, and general constitutional disturbance, the jaundice appearing on the 6th.

Hepatic dulness was much enlarged, extending downwards to a point midway between the umbilicus and false ribs, upwards to within an inch and a half below the right mamma; there was great tenderness over the whole region, specially over the gall-bladder. Did not suffer from any acute pain in the liver. He could not assign any immediate exciting cause, such as cold, a wetting, &c.

Treatment.—Ordered nitro-muriatic acid lotion to be applied as a fomentation over the hepatic region, the part covered by waterproof cloth, to be kept on constantly.

R Acid. nit. mur. dil., ℥ij ;
Sp. chloroformi, ℥ij ;
Infus. gentianæ ad ℥viiij. M.

Two tablespoonfuls to be taken three times a day.

R Pulv. jalapæ co., ℥i ;
Pulv. cret. c. hyd., gr. iv. M.

Ordered two, one to be taken each night.

Placed him upon a slop dietary and directed him to take no stimulants.

March 14th.—Improved. Augmented secretion of urine, deep coloured, loaded with urates, and giving the characteristic bile stain upon linen, and the iridescent play of colours with the nitric acid test. Bowels acting moderately. Repeated the powders, increasing their strength. Other treatment continued.

March 19th.—Stronger and better. Skin losing its jaundiced hue ; bowels well opened ; stools very bilious ; urine lighter in colour, no deposit ; extent of hepatic dulness diminishing, together with the sense of tenderness to pressure or percussion. Appetite improving, so much so that I allowed a return to a meat diet in small quantities.

March 21st. Convalescing rapidly. The subsequent history of the case was one of steady recovery.

REPORT ON SYPHILIS.

By C. R. DRYSDALE, M.D., M.R.C.P.L., F.R.C.S.E.,
Senior Physician to the Metropolitan Free Hospital.

OF late years the fame of Aix-la-Chapelle has risen very high for its treatment of syphilis, and it is important to know what doctrines are held by practitioners of that city.

Dr. Schuster, of Aix, comes to the following conclusions (*Deutsche Zeit. f. Pract. Heilk.*, 1874) :—

1. No general mercurial treatment is required for ulcers appearing after suspicious contact. Local treatment suffices : cleanliness, and the external use of iodoform, in powder or ointment. The reason of this axiom is : We cannot speak clearly about syphilitic infection until its manifestations appear, or generally before from three to five weeks after the suspected connexion ; during the three to five weeks period of incubation we are not in the position to recognise the entry of the syphilitic infection, and therefore there can be no need of speaking of mercurial treatment. If this principle be not clearly maintained, and if a mercurial treatment be commenced at each new ulcer of the genital organs, we shall treat as many people who have no primary affection conducing to syphilis uselessly as those with syphilitic infection.

2. Against the primary induration, with swelling of the glands, we should adopt treatment by vapour-baths and iodide of potassium, since through these appearances it is made clear that the virulent infection has passed through the neighbouring glands and entered the blood, and iodide of potassium is preferable in this stage to mercurial treatment, since experience teaches that when mercury is used too early, it loses its effect when the disease remains a long time, and it requires frequently to be repeated. The body becomes indifferent to mercury, just as after the long use of morphia or arsenic, and in consequence of this the syphilitic appearances of later epochs, when it is the most important remedy, are untouched by it.

3. Against the secondary and tertiary appearances of syphilis (exanthems, gummata, diseases of the bones and internal organs) mercury has its best indications. It is contra-indicated in those amyloid degenerations of the greater or lesser glands (liver, kidney, &c.), united with universal cachexia, which are often joined to the tertiary period : in such cases even small doses cause loss of strength and

salivation. On the other hand, some disturbances of the health, unconnected with syphilis, do not exclude mercury. In acute epidemic diseases occurring with syphilis we must shun mercury ; these diseases already by themselves weaken the syphilis. Tuberculosis in syphilis is made worse by mercury. Pregnant syphilitic women react quite as well against well-conducted mercurial courses as infants suffering from hereditary syphilis ; in pregnant women the fœtus will by this means often be born living and healthy. If, after a certain time, the syphilitic symptoms do not give way, although mercurial appearances show themselves, mercury must be left off ; and here sulphur hot baths are useful in bettering the constitution and the symptoms of the disease : since they free the body from the mercury which has been used to saturation, and help to regulate the physiological processes. Herein, then, we have, in the preparation of iodine, a remedy coming after the mercury to attack any symptoms that may remain.

As to the curability of syphilis, Dr. Schuster speaks next of those who consider syphilis as an incurable disease, which only leaves off with death. During life there is always the fear, even after years of interval, that some new outbreak of the disease may occur. As chief proof of the curability of syphilis, Dr. Schuster brings forward the assertion that a man who has been syphilitic may have a second infection, and fresh secondary symptoms ; such a reinfection is testified to by Köbner's published cases, in which roseola and mucous tubercles appeared twice. Here the first syphilis must have been cured, since a person still syphilitic clearly cannot be reinfected.

As to the question, When may cure ensue ? Dr. Schuster is of Zeissl's opinion in this matter. In the most favourable cases the cure of syphilis requires 3 to 4 months. Such cases are rare. More extended forms require longer time, sometimes two, three, or more years. He acknowledges that there are so-called abortive forms of syphilis, and compares them with abortive cases of typhus and small-pox.

Of special interest is the question, When has cure taken place ? What signs have we which let us know that the cure of syphilis has arrived ? The idea of some practitioners, that the longer the patient remains free from relapse, the stronger is the probability of cure, can satisfy neither the patient nor doctor.

Patients should, therefore, take some baths in the sea, or vapour baths, or Turkish baths, in order to see whether such bring on relapses. If none of these do, there is the more chance of the disease being cured.

Dr. Charles Mauriac, the distinguished and gifted physician to the Hôpital du Midi, of Paris, has written a most important monograph on "Psoriasis of the Buccal Mucous Membrane," which will interest all who know how many difficult points are found in this region. The history of this disease has been hitherto only sketched : it is so obscure and complex an affection. Its diagnosis sometimes presents difficulties which deride the sagacity of the most practised physicians. As to treatment, the results have been nil, or insignificant, although all remedies have been tried.

The lesions, says Dr. Mauriac, which constitute buccal psoriasis are attached to general or local conditions essentially differing from each other. In the great majority of cases these lesions have a character of benignity persisting up to the most advanced phases of the process. But it sometimes happens that the superficial proliferation of the epithelial elements becomes deep, destructive, and invading, and degenerate into very grave epitheliomatous affections.

Psoriasis of the buccal mucous-membrane is not, then, an affection proceeding from the same causes, following the same progress, and presenting the same termination, or exacting the same treatment in all cases. It is most generally a pathological state by which there is translated, according to a process almost always apparently the same, the injurious action of several constitutional diseases on the buccal membrane. It results that this

kind of psoriasis, as it is allied sometimes by ties of causation more or less visible to some of the great constitutional diseases, so each of these will impress on it a special quality, and will classify it in its most natural nosological position.

The affection should not, then, be looked on as idiopathic and purely local except when it is impossible, in spite of the most careful investigations, to discover any constitutional symptoms in the patient.

In the second case cited by Dr. Mauriac, a young officer with psoriasis of tongue had also, in the fifth month of disease, gummy tumours on the tongue. In several cases tobacco-smoking in excess seems to have been the exciting cause of the disease.

The transformation of lingual psoriasis into epithelioma has been pointed out lately by several pathologists. Samuel Plumbé presented three cases of this kind to the Medical Society of London.

The constant anatomico-pathological element which is never wanting in buccal psoriasis is the presence of grey, opaline-white, diffused or circumscribed, regular or irregular, thin or thick plates over the tongue, lips, and internal aspect of the lips.

Psoriasis is the correct nomenclature of the disease, and not ichthyosis, as has been used in England.

The edges and all the upper aspect of the tongue are the regions of the tongue most frequently and deeply attacked. Next come the commissures of the lips, and lastly, the lips.

When the affection develops itself under the influence of syphilis, we almost always find, at the same time as the opaline plates, most accurately marked forms of mucous plates, consisting of slightly raised elevations of the derma, covered by a thick epithelium, under the lips or edges of the tongue.

Dr. Mauriac adds that ulcerated mucous patches and specific erosions of the lips and tongue have a great tendency, when clearly of syphilitic origin, to become covered with a greyish pellicle, more or less adherent to the subjacent tissues, which differs essentially in its aspect from the epithelial plate, which is opaline and horny.

Fissures of the edge of the tongue are very frequent in old cases of syphilis, especially when the disease often appears on the organ with that obstinacy which it has in attacking sometimes without relaxation any point which it has first showed a preference for. During the first phases, these fissures remain insignificant, and consist merely in small inequalities produced by the pits of mucous tubercles which have cicatrised. Later on, ulcerative syphilitic affections, and especially softened tubercles, dig more deeply into the tissue of the tongue and cause losses of substance the repair of which causes deformity much more considerable. And, *a fortiori*, it is the same when gummy tumours of the tongue soften and then cicatrise.

Dr. Bazin, it seems, does not admit that syphilitic psoriasis exists.

Dr. Mauriac says: "Incurability and innocuity appear to be the dominating qualities of the process when it is arthritic or dartrous; curability and innocuity are the properties of syphilitic psoriasis of the mouth, and incurability and malignity in epitheliomatous buccal psoriasis.

As to treatment of buccal psoriasis, Dr. Mauriac advises the bicarbonate of soda in cases where the disease is arthritic.

If the disease be herpetic, he recommends arseniate of soda, and when syphilitic he uses mercury, or, in later stages, the iodide of potassium.

Dr. Mauriac gives a number of most interesting cases to explain what he means by the term psoriasis; and adds an appendix with other cases, and which contains a narration of the debate on Mr. Fairlie Clarke's paper at the Royal Medical and Chirurgial Society in 1874.

Mr. Francis Mason has contributed to the "St. Thomas's Hospital Reports" a most important article on "Infecting Sores on the Lips and in other Anomalous Positions,"

which he has published separately in a pamphlet of fifteen pages. Mr. Mason speaks of the great importance of making a correct diagnosis in such cases, for even at the present day an infecting sore on the lip is not uncommonly taken for cancer; besides which, it has often been thought advisable to excise such a tumour, as in a case where Mr. Quain was consulted. The lower lip seems most frequently affected. Cases are quoted from Stanley, Weeden Cooke, Quain, Adams, Maunder, Bryant, Coote, Watson, Couper, Critchett, Holthouse, Jones, Hutchinson, Churchill, Paget, Drysdale, Murray, Fournier, Hill, and Diday. Eleven sores were on in the lower lip; 6 on the upper; 7 on the hand; 1 on arm; 1 on eyelid; 1 on cheek; 1 on tongue; 1 on palate; 1 on abdomen; and 1 on the thigh. Most of these, we presume, arose from secondary symptoms in the person infecting them.

CLINICAL REPORT OF THE ROTUNDO LYING-IN HOSPITAL FOR THE YEAR ENDING NOVEMBER, 1874. (a)

By GEORGE JOHNSTON, M.D., Master of the Hospital.

THE author said he wished to impress upon the minds of those present that he had no theory of his own to promulgate; his only object was to give an accurate account of the occurrences in the hospital in order that a fair conclusion might be arrived at as to whether or not a large maternity was as safe for those seeking its advantages as for those confined in their own homes. He was happy to be enabled to say that the sanitary state of the institution had been a great deal better during the past year than in preceding ones, inasmuch as although there had been a greater number of deliveries during that period, the mortality was much diminished, being less than half what it was the year previous. On referring to statistics they found that in the year 1869 there were 1,159 deliveries, and 25 deaths from all causes; in 1870, 1,087 deliveries, and 27 deaths from all causes; in 1871, 1,161 deliveries, and 33 deaths; in 1872, 1,193 deliveries, and 20 deaths; in 1873, 1,191 deliveries, and 32 deaths; and in 1874, there were 1,236 deliveries, and only 15 deaths from all causes. The causes of death in these fifteen cases were briefly as follows:—Placenta prævia, 1; apoplexy, 1; convulsions, 1; scarlatina, 3; bronchitis, 1; peritonitis, 3; pyæmia, 1; sloughing, 1; fatty degeneration of kidneys, liver, and heart, 1; typhoid fever, 1; and typhus, 1. The diminution in the number of deaths, notwithstanding the prevalence outside the hospital of a very large amount of zymotic and other sickness (such as scarlatina, typhus and typhoid fever, erysipelas, &c.), was remarkable considering the various circumstances under which the individuals came into hospital—some seduced, others whose husbands had either cruelly ill-treated or deserted them, others, again, who had lost their husbands by death, or who were in an extremely delicate state of health. The diseases from which some of those admitted suffered were acute bronchitis (of which there were 44 cases), jaundice, convulsions, epilepsy, mania, diarrhoea, scarlatina, typhus and typhoid fever, gastritis, &c., thus showing that they were not free from the dangers usually attendant on a large maternity. Dr. Johnston mentioned the case of a girl (a patient in the hospital) who was apparently in the last stage of typhus fever. While in that condition on one occasion she was observed crying bitterly. On being asked the reason of her grief, she replied that she had been seduced, and that her parents had spurned her, that she had no home, and that she did not know what would become of her when she left the hospital. She had attempted to commit suicide twice, but had been prevented carrying out her intention. She was told not to let her prospects be a source of anxiety to her, as

(a) Abstract of a communication read before the Dublin Obstetrical Society on the 9th inst. Specially reported for the MEDICAL PRESS AND CIRCULAR.

she would be befriended, and a home found for her. From the time she received such encouraging news she rapidly began to improve, and eventually became completely restored to health, and employment was found for her in the institution. Dr. Johnston said he particularly referred to this case as showing the great influence which the mind exercised over the body under the circumstances he had described. Its doors were open to everyone—not even a note of admission was required; all that was necessary was proof that the aid afforded by the hospital was really necessary. The low death-rate was attributable to the strict attention to cleanliness observed throughout the Rotundo Hospital, and also to the fact that there was a constant current of pure air permeating the atmosphere of the wards, and so rendering any poison with which it might be charged perfectly innocuous. That was a condition that had been frequently observed by many visitors, who, after examining the wards, wrote in a book kept for the purpose their opinions, which were most favourable. The system now adopted, of not allowing the labour to be prolonged, together with the evils resulting from pressure of the head on the soft parts, which endangered the life of the child and rendered the parent more susceptible to inflammation, these changes not only contributed to the convalescence of the mothers, but, without doubt, saved the lives of the children. In 1874, as had been already stated, 1,236 patients had been delivered in the hospital, and 153 at their own homes; 254 received treatment for various complaints, and 4,927 in the dispensary, making a total of 6,577 relieved in the course of the year. Of the 1,236 deliveries, in 997 the labour was purely natural, terminating within twenty-four hours, and in 40 it lasted over twenty-four hours. A great number of the cases were under the care of practitioners or midwives who, finding the symptoms beyond their own skill, had sent them into the hospital. In 45 cases the ovum was expelled at the sixth month, and in 138 cases the forceps was applied. They had no recourse to the perforator. There were 25 cases of post-partum hæmorrhage, but most of them were of a trivial character. On one hundred and four occasions chloroform had been used in the course of labour. As before stated, there were only 15 deaths from all causes, or 1 in 82½. Nine of the deaths occurred from disease of the zymotic type. In the 138 instances mentioned in which the forceps had been used, such a course had been resorted to as well for the safety of the mother as to preserve the life of the child. One hundred and five of these were primiparæ, of whom 97 lived and 5 died; the remainder were pluriparæ. From their experience in the hospital, they were more and more certain of the great advantage in using the forceps, both for the safety of the mother and child. There were 24 cases of twins, 7 of which were primiparæ. Version had to be performed fourteen times. With regard to post-partum hæmorrhage, he thought that, if possible, there should be some accurate definition laid down as to what it should be considered—whether it should constitute either a slight dash of blood, simply requiring steady pressure on the fundus of the uterus; whether the amount of loss might be such as that in the opinion of the attendant it would be necessary to inject cold water into the vagina or uterus, or to administer ergot or opium; or whether the loss should be so great and the drain continual until the pulse became affected, and symptoms of exhaustion requiring strong astringents, &c., were apparent. As he had before remarked, not a death had occurred in the hospital from this cause, and in the tables appended to his report he had carefully shown the various degrees of hæmorrhage that occurred, and the treatment adopted in each case, so that an accurate idea might be formed. He thought the report clearly showed that a large maternity was not necessarily the centre of zymotic disease. In no one instance where contagious disease was brought in by a patient was that disease ever communicated to any other patient in the hospital. When they bore in mind the vast amount of mortality from zymotic diseases which had and still prevailed in the city and suburbs of Dublin, it must be allowed that sickness was engendered elsewhere than in the hospital, and that patients seeking shelter there ran less risk by entering it than if they were confined in their own homes (where too often filth and bad air were to be found), and were fully as safe as if they had been confined in isolated dwellings.

HOSPITAL Saturday in Exeter yielded £210 17s. 3d. The boxes of the London fund were lent for the collection.

Transactions of Societies.

DUBLIN OBSTETRICAL SOCIETY.

THE third meeting of the present session took place on Saturday the 9th of January,

Dr. LOMBE ATTHILL, President, in the Chair.

AN OBSTETRICAL ANTIQUE.

THE PRESIDENT stated that he had the pleasure to present to the Society the cast of a sculpture of very great interest. The cast was presented to the Society by Mr. Bibby, a surgeon of London. The President said the Society was under great obligations to Mr. Bibby for the presentation, which was a cast representing a parturient woman. The original was dug at the Temple of Venus, at Cyprus. Four figures were represented—the mother, on a stool, an attendant behind her, supporting her with her arms, and the nurse in front, the newly-born child in her lap. Portions, however, of two of the figures were missing. The cast was particularly interesting, as illustrating the mode of delivery on stools as mentioned in the Book of Genesis. The President read letters he had received from Mr. Bibby on the subject of sending the cast to the Dublin Obstetrical Society, in one of which he stated that, having dissected many years ago in the Dublin and Richmond Schools, he felt anxious to send the Society a small professional acknowledgment, and Mr. Bibby had forwarded the cast to the Society free of charge. The President mentioned that he believed the date of the Temple of Venus was supposed to be about 300 years B.C.

Dr. J. A. BYRNE said the cast recalled to his mind a statement made to him by a highly respectable nurse, now in Dublin, but who had been for a long time living in Greece, where she held a position of responsibility. She had told him that she had seen her former mistress, a Greek lady, delivered on one or two occasions. It appeared that at the present time the Greek physicians used a similar mode of delivery to that shown in the cast. They put the female upon a kind of raised chair, with a semi-circular opening in the front—he supposed to accommodate the fœtus. He thought it might be of interest to the Society to know that the present Greeks follow the old method of delivery.

Dr. CHURCHILL moved that the cordial thanks of the Society be given to Mr. Bibby for his gift. The method of delivery by stool or chair was, no doubt, extremely ancient, but it was not ancient in the sense that it was not modern, for he saw on one occasion in Edinburgh a chair that had been used in the time of Dr. Hamilton.

Dr. JOHNSTON, Master, then read the

CLINICAL REPORT OF THE ROTUNDO LYING-IN HOSPITAL FOR THE YEAR ENDING NOVEMBER, 1874,

being the sixth year of his mastership, which will be found at page 48.

In the succeeding debate,

THE PRESIDENT said that the valuable report just read by Dr. Johnston proved his premises, that in a properly managed lying-in hospital, where attention was given such as that bestowed upon the Rotundo by Dr. Johnston, the deaths from puerperal causes might be reduced to a minimum, or quite as low as in deliveries occurring outside its walls. He (Dr. Athill) did not think a more favourable report could have been given by any practitioner—whether in private or hospital practice—in the kingdom. Dr. Johnston's success certainly proved the excellence of his practice. At the same time he (the President) must say that there were certain portions of Dr. Johnston's practice which ought to be discussed, and he was sure Dr. Johnston would with very great pleasure hear any observations that might be made. Prominent among them was his use of the forceps. His practice was so successful that they could hardly condemn recourse to it once in ten times, and nothing could exceed the beneficial results which Dr. Johnston had proved to have accrued. He (the President) would, however, be sorry, notwithstanding the favourable results detailed in the report, that the free use of the forceps should be promulgated among inexperienced people. What was quite safe in skilful hands might be very unsafe in the hands of an inexperienced practitioner. He was strongly in favour of the long double-curve forceps which Dr. Johnston was in the habit of using, although he knew many who considered the straight superior.

Dr. CRONYN had seen Dr. Johnston use the double-curve forceps when the os was not dilated more than the size of a halfpenny. The patient was a primipara, and on the occasion to which he referred Dr. Johnston used the instrument apparently with the greatest ease, and delivered the woman of a large child. For two or three hours previously the dilatation of the os had not advanced, though the pains were good—the labour was, in fact, proceeding very slowly. He (Dr. Cronyn) was forcibly impressed with the way in which the forceps had been used by Dr. Johnston. He (the speaker) was originally inclined to think that the use of the instrument was a hazardous proceeding, but after having seen it applied as he had stated he became a convert to it.

Dr. HENRY KENNEDY, who had been afforded an opportunity of seeing all the cases of zymotic disease that had occurred in the Rotundo Hospital during the past year, remarked that there was distinct evidence in four-fifths of these cases that the females had brought in disease before the delivery came on at all. He thought that was a most important point as bearing on the question of large maternities. If the patient exhibited signs, which were quite evident to anyone who inquired into the point, of sickness independent of pregnancy, he had no hesitation in saying that the stage of delivery was quite sufficient to bring into life a disease which many had supposed had only been engendered in the hospital. Dr. Johnston had alluded to one remarkable case—that of the female who presented all the symptoms of typhus fever. It was remarkable as regarded what he wished to call "treatment." In that case the mental had proved of much more use than the physical treatment. An extraordinary change occurred when the girl was told that it was likely that she would not be forsaken or neglected, and her recovery was unusually rapid. Some of the patients manifested signs of disease a few hours after admission, showing that contagion was entirely out of the question, and that poison was in the system before they entered the hospital.

Dr. KIDD wished to know whether, in reference to the use of the forceps before the os was fully dilated, it had ever been found impossible to deliver the child after the instrument had been applied?

Dr. JOHNSTON replied that in no one instance was the forceps applied and the child not delivered. As a proof of the advantage of the double-curve forceps, he would mention that within the last month a woman from Denbigh, North Wales, came under his care, having in a former confinement been delivered by means of perforation. He used the double-curve forceps, and after a considerable amount of dragging he delivered her. It would be difficult to conceive a child more twisted than hers was—so much so that he feared it would not live. It, however, left the hospital quite well with its mother. That was one of the results of the use of the double-curve forceps. Once a grip was obtained with one of these, it would never yield. In another case, that of a woman with her ninth child, there was a depression on the parietal bone of the child of $3\frac{1}{2}$ in. by $1\frac{1}{2}$ in. That child also went out with its mother well on the eighth day. He believed he was nearly three-quarters of an hour delivering her.

Dr. KIDD thought this one of the most interesting matters that had been brought before the Society for a very long time. There was such an immense amount of matter contained in Dr. Johnston's report that he felt unable to grasp it, and therefore hesitated to speak with regard to it. In his own experience, he had sometimes tried to deliver the head with the forceps before the os was fully dilated, and he had many times succeeded in doing so. He had also succeeded in applying the forceps, and been obliged to give up the use of it, because of its slipping. The point he meant to raise was not in reference to the peculiar forceps used, whether straight or curved, because he did not think that so very material, but as to the amount of force it was necessary to use to draw a child from an undilated os uteri. If the os were dilatable, he knew they could, with a very moderate amount of force, effect delivery. But that was the very case in which probably it was not necessary to use the forceps or any artificial means of delivery. If the os were not dilated, if the membranes had ruptured very early, and they had a rigid os uteri, and applied the forceps—there, he thought, they would have to use an amount of force which would very probably injure the patient. He knew, however, that Dr. Johnston had stated that where the os was rigid he made use of the ordinary means to counteract that rigidity. He (Dr. Kidd) confessed that, to his mind, the great difficulty to understand was the amount of rigidity that it was safe to attempt to overcome with the forceps. He had seen a great deal of force used sometimes

with the forceps, more force than he thought was justifiable, and more than that to which he would like to have recourse.

Dr. M'CLINTOCK said the all-important and salient feature of Dr. Johnston's able and elaborate paper was that bearing upon the use of the forceps before the full dilatation of the os uteri, and that, as it were, would open up and would constitute a remarkable epoch in the history of midwifery. It opened out a new era with regard to practice, because it was so much at variance with all the maxims, principles, treatment, and practice laid down by the great and acknowledged authorities in obstetrics. But they were not on that account to reject or repudiate it. Dr. Johnston stood in this very strong position—that he advocated a practice which he had largely tested and tried, and by which he was able to show most satisfactory and gratifying results. At the same time he (Dr. McClintock) must say that he was such an obstinate conservative that he thought Dr. Johnston's practice and results would go this far in his mind satisfactorily to show and demonstrate that long forceps might be applied with perfect safety to the mother and child under circumstances where formerly they would entirely have shrunk from using them. That was a great step and a great fact to establish, that under circumstances of a peculiarly pressing nature to the mother and child, to feel that they had recourse to forceps which might be resorted to with perfect safety and success to the two concerned. He fully admitted that, and agreed with Dr. Johnston, and acquiesced in his results in so far as that. Even though he did no more, that was a great step, and most important. With regard to the particular circumstances under which the forceps should be employed, where the os was only partially dilated, there, he (Dr. McClintock) thought, the rule should be laid down with more precision. They knew that the first stage of labour might be prolonged to great length with perfect safety, and in fact, impunity to the mother and child, and he felt satisfied himself that if there was any rigidity of the os uteri, there the use of the forceps would be a very hazardous proceeding. But in cases that sometimes occurred, where prolapse of the funis took place, or where any sudden emergency arose, calling for delivery to save the mother, if she was imperilled, or an attack of convulsions came on, then it was very comforting to know that they might resort to the expedient with safety and advantage. He could hardly, however, conceive a case of simply tedious labour where a resort to this expedient would be justifiable. It was one thing to say that the forceps had been used under such circumstances with safety, with great care certainly, in a few cases, and in most experienced hands, such as Dr. Johnston's; but to lay it down as a rule, or to attempt to lay down a rule that, because labour had been tedious in the first stage, resort to the forceps had followed, would be fraught with danger, and if such a practice were acted upon by inexperienced or incapable practitioners or young men, it might be productive of very serious results. He quite agreed with Dr. Kidd that the report embraced so many subjects of great importance that it was impossible to take in everything as it was read, or touch upon almost any of the many interesting points which it embodied. One thing struck him, and that was the large proportion of primiparæ out of the entire number of deliveries. The entire number was 1,236, and of that there was the large proportion of primiparous persons of 380, or nearly one in three. To show so small a mortality as that among the deliveries for the year, where there was such a large proportion of primiparæ, spoke most highly for the success of the practice pursued, and for the healthfulness of the institution during the period embraced in the report.

Dr. JOHNSTON then replied. With regard to what had fallen from Dr. Kidd as to the amount of force necessary to make the os yield, he could only say that, once the forceps were got in, of course it was not, as he told the students, like drawing a cork out of a wine-bottle; but care and judgment in extraction must be used, until they gradually got the os expanded—and it was wonderful in how short a time the os would become fully expanded. Concerning what Dr. McClintock had observed as to the importance of using the forceps in the first stage, he (Dr. Johnston) must repeat to them what he had mentioned before, that it was in consequence of a case where there was early rupture of the membranes. Dr. McClintock had stated that the first stage might be continued with little danger. A case to which he (the speaker) had referred induced him to do so, and it was a case where, according to the old rule, a warm bath was used, and the patient given stimulating enema. When he again saw her he found that the os was not fully dilated, though he could

extend it. He delivered her with a forceps. On the third morning, however, she was found in a state of collapse, and died in half-an-hour. At the post-mortem examination they discovered a complete separation of the cervix from the body of the uterus. That one circumstance had induced him to make the bold step he had taken, and certainly he had no reason to repent of having done so.

The Society then adjourned.

A N S W E R

TO THE

"DISSENT FROM THE PROPOSED SUPPLEMENTAL CHARTER SOUGHT FOR BY THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND."

King and Queen's College of Physicians in Ireland,
Dublin, December 22, 1874.

To the Right Honourable SIR MICHAEL HICKS BEACH, BART.,
M.P., Chief Secretary for Ireland.

SIR,—Referring to the Memorial of the President and Fellows of the College of Physicians for a Supplemental Charter, and to a Dissent from the prayer of the said Memorial on the part of five of the Fellows, I am directed by the President and Fellows to respectfully request you to present the following considerations to his Grace the Lord Lieutenant:—

1. That the President and Fellows in seeking permission to the ballot in elections are not seeking any unreasonable or unprecedented powers, as a perusal of the "Dissent" might lead one to suppose, but are merely asking a privilege which is already enjoyed by nearly all the medical corporations and chartered societies in Great Britain and Ireland.

2. That the College in seeking for the use of the ballot in voting, accepts the principle that the majority of votes shall decide the result.

3. That the number of Fellows resident in Dublin and its vicinity, and attending, with more or less regularity, the meetings of the College, is forty-five, of whom only five have dissented from the provisions of the proposed Charter.

4. That during the forty years when the practice of voting by ballot prevailed, no complaint to the Visitors was ever made against the practice.

5. That the ground of complaint in the recent visitation was not against the use of the ballot, but against the principle which required a majority of four-fifths of the voters to carry the election.

6. That many of the objections to open voting which led the Legislature to enforce the use of the ballot in Parliamentary and municipal elections equally apply to open voting in such a corporation as the College of Physicians, and that besides there are many objections special to the collegiate elections to which open voting is subject.

7. That the odium to which a voter exposes himself, say in a Parliamentary election, by voting for one candidate in preference to another, is not nearly so great as that which attaches to a voter who, in the exercise of a conscientious conviction, votes against men where the number which might be elected is unlimited, and where the question is merely one of fitness.

8. That while freely admitting the assertion of the Dissentients, that the duty of co-opting new Fellows into the College is a trust, for the exercise of which the existing Fellows should be responsible to professional opinion, it is at the same time one in which they should be protected from the undue influence which could so easily be exercised upon them by candidates, however undeserving of the Fellowship, who were supported by a powerful political, religious, or social party.

9. That the system of open voting is subject to serious objections where the body is relatively small, as in the College of Physicians, because the introduction of the personal element into elections where the parties are afterwards brought into close and constant intercourse is almost sure

to lead to animosities of a permanent character that would have the most injurious influence on the future working of the College.

10. That one of the effects of the operation of open voting would be to deter many of the most valuable members of the College from taking an active part in the management of its affairs.

11. That the analogy which the Dissentients seek to establish between the mode of creating Fellows in the College of Surgeons and in this College, does not apply, inasmuch as the Fellows of the College of Surgeons do not constitute the governing body, all the powers of the College being vested in the Council, to which, as to all the offices of the College, election is by ballot.

12. As the Dissentients appear to make it an objection that in the King and Queen's College of Physicians there are now no more than fifty-five Fellows, the President and Fellows find it necessary to reply that in the University of London, a great and most important institution, the number of Fellows is only thirty-six; and that in the other Colleges of Physicians, in the Colleges of Surgeons, the Glasgow Faculty, and in all the incorporated scientific and literary societies in which the number of fellows or members is unlimited, there is a council, or other governing body, of a small precisely defined number, usually twenty-one, but in the London College of Physicians but eighteen, and in the Edinburgh College of Physicians only seven. And that besides there is also, in nearly all those bodies, a provision that a candidate for admission should have much more than a bare majority of votes in his favour, some requiring three-fourths, and others four-fifths of those present and giving their votes.

13. That the Fellows disclaim in the strongest terms any desire or intention to use the proposed vote by ballot to the disadvantage of candidates who may happen to differ from them in religion or politics.

14. That of the five candidates who were rejected under the bye-law, since declared illegal, four were Roman Catholics and one was a Protestant; but there was this difference between them—every one of the four Roman Catholics would have been admitted had a simple majority, as is now sought for, carried the election, but the Protestant would not.

15. That none of the three Roman Catholic Fellows whose names are appended to the Dissent have any reason to complain of the effect of secret voting, since by it one was elected to his Fellowship without a single black bean; another was for five consecutive years elected to the Presidential Chair—an honour unprecedented in the annals of the College; and the third has been four times elected Censor, and has been once appointed Vice-President.

16. That the bye-law which the Visitors have pronounced illegal was framed for the sole purpose of preventing the indiscriminate admission to the Fellowship of Non-Graduate Licentiates—a measure which the College considered the Act 25 Victoria, chapter 15, gave them full power to guard against, since in its concluding paragraph it specially enacts that the Fellows shall admit Licentiates who are not Graduates "under such limitations as to them may seem fit."

17. That the College desires to have the power to create an order of Members similar to that which is possessed by the Royal Colleges of Physicians of London and Edinburgh, inasmuch as there are numerous valuable medical appointments in England which can only be held by Fellows or Members of a College of Physicians; from these the Licentiates of this College are necessarily excluded, and it is in consequence of remonstrances addressed to the College by various Licentiates who have suffered from this disability that this power is now sought, whereas not a single Licentiate has objected to the creation of the new order.

18. That with regard to the statement of the Dissentients, that they speak in behalf of 1,200 Licentiates, the President and Fellows merely remark that, notwithstanding the length of time the subject has been under consideration, the Licentiates have addressed no communication to the College on the subject, and therefore the College is driven to the conclusion that, in professing to protest in the name of 1,200 Licentiates, the Dissentients act on their own responsibility, and without the authorisation of the Licentiates to whom they refer.

19. That in the Draft Supplemental Charter it is expressly provided that in the creation of said order of Members the rights of all existing Licentiates are to be preserved; and that if the College failed to do so, the Licentiates would enjoy the right of appeal to the Visitors of the College.

I am directed respectfully to beg that you will bring these considerations under the notice of His Grace; and the Presi-

dent and Fellows hope they will lead him to recommend Her Majesty to grant the Supplemental Charter sought for by the College.

I have the honour to be, Sir,
Your obedient servant,
J. MAGEE FINNY, M.D., Fellow and Registrar.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, JANUARY 20, 1875.

THE BIRMINGHAM CONFERENCE ON SANITARY REFORM.

THE note sounded by Dr. Letheby in his paper on the health of towns in November last has not been allowed to die away without awakening some echoes. So many startling truths as those enunciated by that learned chemist and hygienist could not, we felt assured, fail to make an impression on the more thinking of our public men. It has been the good fortune of Birmingham to possess in its Mayor a gentleman of great scientific culture, and hence that city has become the pioneer of what we trust may be a great and national movement in the direction of rendering our great cities less destructive to life and health than they have hitherto been.

On Thursday last, the 14th inst., a large meeting of ladies and gentlemen assembled at Birmingham, at the invitation of Mr. Joseph Chamberlain, Mayor of that city, and we read that among those present were to be seen Sir Sydney Waterlow, Dr. Buchanan, Mr. Humphry Sandwith, Dr. Frankland, Dr. Taylor, of Liverpool, Mr. Pritchett, of Huddersfield, and many other able men. To read the address of the Mayor on that occasion is a treat to all lovers of public health inquiries, and it redounds much to the honour of Birmingham, that the Town Council of that city has had the intelligence to choose for its chief magistrate so very able a man. It is true, as Mr. Chamberlain remarks, that there is a want of a proper sense of the relative importance of the question of public hygiene in the mind of the nation at large. Men are early stirred by an exceptional calamity, such as a fire, explosion, or shipwreck; but sanitary defects, which prematurely carry off hundreds, and even hundreds of thousands, are regarded as common-place, just on account of their magnitude, and because they are always with us;

and we adopt a kind of fatalistic indifference, as if such gigantic evils were inevitable. When such an outbreak of disease as lately occurred at Over Darwen takes place, public attention is directed to the locality for a short time; but apathy soon spreads over our minds again. It is only when local authorities, says Mr. Chamberlain, are assured of the hearty co-operation of the people that they can properly exercise the powers entrusted to them; and it is only quite recently that the Legislature has invested local authorities with the powers requisite to enable them to carry out any great scheme for benefitting the towns over which they preside. Then again, public hygiene is a branch of medicine quite in its early infancy as yet.

The ordinary public, says Mr. Chamberlain, is by no means aware of the enormous waste of life, which is always going on, and of the terrible consequences to sanitary, moral, and pecuniary interests. When we find that the rates of mortality vary from a minimum of something like 16 per thousand to a maximum of 38 to 40 per thousand, it is clear that immense evils exist, which cannot be possibly called irremediable by human forethought and skill. The death-rate of the rich and poor is significantly most unequal. Dr. Lee, Medical Officer of Health for Manchester, states that the average age at death among the Manchester middle-class is 38 years, whilst the average age at death of the labouring classes is 17; these same ages at Liverpool being represented as 35 against 15. “It thus appears,” says Mr. Chamberlain, “that the well-to-do classes have a lease of life more than double the value of that falling to the lot of the less favoured of their fellow-citizens.”

Then, again, for every 100,000 infants under five years of age, living in favourable districts, 2,400 die; whereas in Birmingham the number is increased to 9,500; in Manchester, to 11,800; and in Liverpool to 13,000. Who is there that, after reading these awful statistics, can refuse to see that Mr. Malthus was right when he called large cities and unhealthy occupations some of the *positive checks* to population, which must always exist whenever ill-educated persons trust too much to the supposed benignity of nature in its dealings with our race. In great towns infants die prematurely in the proportion of 6 to 1 to the number dying in healthy country districts. Mr. Chamberlain quoted the estimate made by Dr. Lankester, that every year there perish from preventible disease in England and Wales no less a number than one hundred thousand, which estimate is confirmed by Dr. B. Carpenter. What in comparison to this are all the railway and steamship accidents in the world?

And, then, it is said with truth, that every person actually dying represents six persons suffering from some disease, which, in the case of children, may be rickets, consumption, and zymotic disease, and in grown-up persons may so often be the result of bad air, over-work, and preventible causes connected with house-building and the occupations of the operative classes. The ignorance of the poorer classes is in great measure kept up by the conditions of life they lead. “In innumerable houses,” says Mr. Chamberlain, “decency is but an empty name, obliterated from the list of the virtues.” Can it be wondered at that people brought up so filthily should be capable of such great brutality as we are shocked to hear of in this

civilised country. Large cities, like Manchester, Birmingham, and Liverpool, are, in our eyes, horrible cruel machines for destroying the health of the vigorous countryman, who migrates into them, after being brought up by some very poor parents in the over-crowded rural districts of England. To talk of the splendid achievements of the spinning-jenny or of the manufactories of Sheffield without taking into account the amount of ruined human beings, who are sent to an early grave by the present factory system, would indeed be unbecoming in a medical journal. The wretched condition, sanitary and moral, of the city of Glasgow, might drive us all into scepticism as to the benefits derived by the poorer classes from the spread of science, were it not that, as yet, there has really never been any real attempt on the part of the scientific classes to grapple with the question of the mortality caused by large towns and unhealthy occupations.

Dr. Letheby's onslaught on the drivelling of the official who does the literary part of the Registrar-General's reports has come just at the right time. It finds the nation in no mood for political excitement, and hence able to attend to any scientific doctrines which may be put forward by those who understand such questions.

In the first place, then, we would remark that one cause of the large mortality of our manufacturing cities is the presence of such a multitude of infants and young children in these cities. Women marry as young in Liverpool, Manchester, and Birmingham as they did in Ireland when the potatoes were plentiful, before 1848, or, indeed, as young as they do in the United States or in Australia. The cause of this is clear enough. The mother is able, by her work in the factories, to become a bread-earner at an early age; and, among the poor, to get a living is the immediate incentive to reproduction. Hence the multitude of unfortunate infants born only to die, offspring of the Lancashire operative women. To explain their position in life to these young and thoughtless girls, and to show how impossible it is to nourish and properly educate an infant in the midst of their toil and non-domestic habits should be the aim of philanthropists in the manufacturing districts.

This is the primary cause of the very high death-rate of Birmingham: and as human beings are, after all, rational, it is clear that a time will come when it will be seen that over-procreation is the main cause of this over-crowding. As to the providing of proper houses for the working classes, this is a most laudable enterprise, and Birmingham is, indeed, much in need of good and clean houses, with water supply and something like the London system of drainage, which has done so much of late years to banish typhoid fever from the metropolis.

But, whether in London, Liverpool, Glasgow, or Birmingham, it must be confessed that poverty, as Mr. Chamberlain says, is the main antecedent of a high death-rate. Talk as we like, there is always a condition of indigence, where the population sunk in it will refuse to attend to anything, save the more immediate wants of the stomach and of obtaining shelter. It is well known that it is quite impossible to prevent very poor people from crowding their families into rooms where the cubic contents of air are much below what is requisite for health. No medical officer can be found who can enforce the rules for cubic

space in private houses with rigidity. To do so would be to force a large number of the poorest classes to pass the night in the open air.

It is to be hoped that the mayors of other towns in England who accepted the invitation to the Birmingham Conference may soon imitate the excellent example set them by Mr. Chamberlain. The only true aim of morality is to make man happy and long-lived. It is most immoral to allow so many miserable quarters to exist in all of our large cities, places where human life is a sordid, unhappy lot, compared with which the existence of a sheep in a good pasture seems to us a paradise. Why, we ask, is it our own race alone of all animals is to be destined to such an amount of suffering? A farmer who should overstock his farm in the way we overstock our cities and hives of industry would be thought to be no judge of animals; and our scientific writers on public health will always stand accused of incompetence and ignorance until they offer their fellow-citizens some better remedies for early death and over-crowding than those which have been put forward by fashionable State doctors during the past half century.

RECENT DEBATES UPON ALCOHOL.

As a result of the recent *Whisky War* in the United States, a series of discussions have taken place in the great western Republic upon the subject of alcohol as a food. The New York Neurological Society has had quite a number of field days upon this important topic; and, not content with this subject having been brought on the *tapis* of the Society, a Committee has been formed, consisting of Dr. Hammond and other able men, to come to some conclusion as to what becomes of alcohol when it enters the blood, and whether it is a food or not.

Pending the decision of the Committee, an esteemed physician, Dr. Willard Parker, of New York, asks the following very important questions:—Does alcohol, when injected into the body, become assimilated and produce force? Why is the temperature lowered when alcohol is injected? Why do all persons in very high latitudes find that they cannot take alcohol when the cold is intense? How is it that persons who have to do very hard work so often break down when they attempt it on beer and spirits? And how is it that insurance companies find that the average life of teetotallers is about 64, whilst that of drunkards and moderate drinkers is 35 years and 6 months? How is it, asks Dr. Willard Parker again, that fifty per cent. of the idiots in asylums and idiotic schools have drunken parents?

These are, indeed, hard nuts to crack for the school of Todd and his most able disciple, Anstie; and this seems to have been the opinion of the six gentlemen who took their stand in Exeter Hall, London, recently, against alcohol. Mr. Clark asserted in that demonstration, which took place on the 27th of December last, that all the forces in the body are decreased instead of being increased by alcohol. Dr. C. Drysdale, from experience, alleged that beer-drinkers had a worse appetite, lost their sight earlier, and lived a shorter time than water-drinkers. Dr. Gilchrist showed the incurability for the most part of dipsomaniacs. Dr. Reid said his treatment

of disease was almost entirely without alcohol. Dr. Rolston showed the improvement caused in the health of the navy by knocking off the grog ration and giving money instead. Dr. Russell in the same way, having been trained in the United States, had come to treat disease quite without alcohol successfully.

Dr. B. W. Richardson has been lecturing, in December last, on alcohol, to the Society of Arts. He remarked that alcohol was of no value to any animal but man. Egypt claimed the discovery of wine for Osiris, Greece for Bacchus, and Rome for Saturn. It seems, according to Richardson, that a good three-quarters of the old world knew no more of wine than of the people who invented it, until they were taught to know it. The ancient wines seem to have been a very diluted solution of alcohol. The ancients also knew how to make beer as well as wine; but it was only in the ninth century that beer was treated with hops, which tend to preserve the fluid, as well as flavouring it. The malt liquors of the last century appear to have been stronger than those of the present century.

At a recent meeting of the Medical Society of London a few words of discussion upon the subject of alcohol took place after the reading of Dr. Routh's paper on "An Epidemic which arose from Drinking of Impure Water." A most able and eloquent speaker, Mr. Brudenell Carter, is reported to have said that teetotallers should point out where good water was to be had, when they spoke so in favour of their tenets. Dr. Crisp thereupon observed that teetotallers were well known to live much longer than moderate drinkers, as was shown by assurance companies' statistics. He had been a teetotaler during his life.

We notice that in a popular work on public and private health, written by Dr. Milner Fothergill, the author takes rather a high stand against the teetotal party, and alleges that alcohol is so much of a food that innkeepers in Germany charge non-drinkers more for their dinner than ordinary beer or wine-drinkers. He says that alcohol is changed in the tissues, and gives force to the body, and that it is, in short, an error in diet to be a teetotaler. Such views are at any rate clear. Well, after all these differences of opinion among doctors, who is to decide in these days of universal scepticism? Certainly not we, who write impersonally. This is far too grave a subject to be dealt with by a pen wielded by any author, however capable, who does not append his signature, to be taken *quantum valeat*. This much we will, however, venture to say: it is quite clear that the time has now arrived for vigorous and oft-repeated discussions as to the nature of the physiological and pathological effects of the ingestion of alcohol, in small quantities and in larger doses, long maintained.

We want lamentably accurate statistics concerning the number of persons who drink beer, wine, and spirits, in any given locality; and the result of these habits on the longevity of the parties as compared with that of the very few who do not consume some form of alcoholic fluid in modern days, and in such wealthy states as England, France, or Germany.

We cannot help thinking, however, that the example of the ancient world shows clearly enough that the distillation of spirits was an unmixed evil to mankind, except in so far as alcohol has been made use of in the manufacture of

various chemical utilities. The ancients, surely, were happier than we are, in their sublime ignorance of the existence of such terrible drinks as whisky, gin, rum, &c. The victims of spirit-drinking are indeed among the saddest spectacles of human degradation the physician has ever to contemplate. Careless of their own lives, heartless, brutal, and wicked, the poor votaries of the whisky-bottle haunt the hospital and the workhouse; and the door-steps, even on the coldest night in winter, are but too often the only beds such unfortunate specimens of our race can afford.

We heartily concur with the fulminations against spirit-drinking so eloquently made in the French House of Commons two years ago by a medical deputy; and we cannot believe that there exists a single physician of experience who would not be found to say God-speed to any legal and fair attempts that might be made by well-meaning societies to lessen the vice of spirit-drinking.

But then comes the difficulty. Admitting that spirits are so noxious when taken in their naked condition, when does the dilution of alcohol, as it occurs in beer and wine; cease to be hurtful—when taken every day for a number of years? It is to this point that we sincerely trust attention may soon be directed in our various medical discussion societies.

The value of alcohol as a drug is also an important matter; but, we submit, not nearly so important as the one we have indicated in the preceding paragraph. After all, disease ought to be the exception and health the rule, if we could find out how to live according to the laws of health. Hence, to inform the world as to what it should do with regard to the daily use of alcohol were indeed a most valuable use of the time of some of our foremost debating champions.

Last year we remember to have listened with great interest to long debates on cancer and on pyæmia in the Clinical and Pathological Societies of London. The Société de Chirurgie some years ago had similar long and oft-repeated talks about syphilis and its treatment. If, during this session, we could hear a similar debate upon the vexed question of how, when, and where spirits, wine, and beer were admissible for the healthy and the sick, we should say that public hygiene would be advanced in some measure. And the debates in the United States are, we believe, certain to have an echo in the old country before long. Finally, we cordially dislike all legislation on such matters. Science is by no means so pronounced in its teachings as to permit of the majority coercing the minority in such matters as the consumption of alcoholic drinks.

THE IRISH COLLEGE OF PHYSICIANS.

We have refrained from any discussion of the important controversy which now engages the Fellows of the College of Physicians in Ireland awaiting the reply of the Fellows to the formidable "Dissent" which issued from the pen of five of the leading members of the College, and which was published in our columns on the 9th of December last. To-day we give *in extenso* the "Answer," and we believe that it will receive from our readers as full a consideration as they gave to the first document. Having given it all the attention which its importance deserves, we are unable to modify in any way our unequivocal condemnation of the ballot as a test for the admission of Fellows to that or any other College; and we repeat what we have previously said, that "the power of a few to bar the entrance of new comers into their conclave is perfectly comprehensible and defensible in a social community where every man is entitled to select his associates with regard solely to his own feelings. But such a power is entirely out of place in the administration of a qualifying body where no consideration but the advantage of the profession and of the College should enter into the calculation."

The College justifies its desire for the perpetuation of the ballot system by alleging that it "is merely asking a

privilege which is already granted by nearly all the medical corporations and chartered societies of Great Britain and Ireland." This statement is based, no doubt, upon the Report of a Committee of the College which lies before us; but on a careful perusal of that report we have been unsuccessful in finding a single case of a corporation in which the ballot was used under circumstances strictly analogous to those of the College of Physicians. We find therein instances of ballot in the election of officers of a College; of ballot as a secondary qualification after examination; and of the use of the ballot as an exclusive test in some societies; but we have found no precedent for the exclusion from, or admission of any person to, a legal medical or surgical qualification solely by the votes of those who already hold the degree. We do not think it necessary to discuss the pleas of the College in favour of the ballot as a general question, because we hold that the fact that a registrable medical qualification is the matter dealt with deprives these arguments of any force whatever. A medical certificate of competency registered and recognised by the law cannot, we take it, be denied to any man on the ground that he is not acceptable to the tastes of those who hold the certificate.

It may be argued that the Fellowship of the Irish College of Physicians is more in the nature of a seat on its administrative council than a high medical qualification, and we undoubtedly agree that the system hitherto has caused it to occupy this position, but we cannot admit that it occupies it naturally, or that new Fellows should be excluded in order that it should preserve that position. We have always been of opinion that the vesting of the administration of a College in the whole body of its Fellows was wrong, and we don't think that it was originally contemplated in the Irish College of Physicians that it should be so, and as long as the difficulty can be readily met by the appointment of a council, we do not think that the body of Fellows ought to be restricted in its extent in order that the administrative efficiency pertaining to a small number should be maintained.

We are aware that a proposal to form an administrative council, and thus remove the difficulty which exists to the enlargement of the body of Fellows, was submitted to the College, and was rejected partly by the vote of those gentlemen who now object to the narrowness of the College.

We cannot undertake to-day to deal with the subject as regards the establishment of a class of members intermediate between the Licentiate and Fellows, but we cannot leave it without repudiating in the strongest terms the attempt to make this a religious question. We believe that the representation that the Fellows are animated by such a prejudice is entirely untrue, and that it is used merely to throw undeserved odium upon them and their proceedings. We cannot prove this part of the case more perfectly than by a republication of the following extract from an article in the *Evening Post*, which is *par excellence* the Ultramontane newspaper of Dublin:—

It would appear from the charges made that the College is so anti-Catholic that they introduced the ballot, and now desire to restore it, in order to exclude Catholics. It was with this view, and in a spirit of recognition of the advanced leaning to liberality, that we deprecated these unqualified assaults. We shall now, in justice to our views, cite proofs in support of our opinions. On 20th May, 1839, a resolution was "unanimously" adopted by the Fellows, thirteen present, demanding a repeal of the Act of 1800, which virtually excluded all Catholics, few of whom held a University degree. Yet at that date there was not even one Catholic Fellow in the College. Again, in 1861, when the agitation was revived to effect that repeal, which was carried in 1862 by the direct action of the College, there were only three Catholic Fellows. Now we come to elections. In 1843 Dr. (now Sir Robert) Kane was almost unanimously elected, there being only a solitary black bean against him, all the electors being Protestants. In 1855 Dr. (now Sir D.) Corrigan was unanimously elected an honorary, and the following year a corporate Fellow; while Sir Dominic was

three years unanimously elected president, and two other years by majorities, although he and Sir Robert Kane were the only Catholic Fellows. Nay, more, we have searched the roll of presidents for the past 182 years, from Sir Patrick Dun, in 1693, to the present year, and we find no other instance, save that of Sir Dominic Corrigan, a Catholic, in which the same person was elected "five successive years" (1857—63) as president. It is but right and just to acknowledge these facts, which are as creditable to the growing liberality of the College as they are to his own eminent professional merit. Again, in 1861, Dr. Lyons was "unanimously" elected to the Fellowship, the protection of the ballot, notwithstanding; while in 1864, Dr. Cruise, the third of the Catholic Dissenters, was elected, the bye-law of 1862 notwithstanding. Here were four Catholics thus elected by Protestants. In 1866, Dr. Hayden was elected, the ballot and the bye-law of 1862 existing. These facts are creditable to the Protestant Fellows who voted for him, and demand honorable mention by Catholics. In October, 1865, two candidates were proposed, a Presbyterian and a Catholic, when the latter obtained a majority of the votes, while the Presbyterian was in a minority. The bye-law of 1862—one black bean in five—however, led to the non-election of the Catholics. Again, in October, 1868, two Catholics obtained each a majority of votes, but lost their election under the same by-laws. Lastly, in October, 1869, thirty-five Fellows present, Dr. MacSwiney had eighteen white against nine black beans, eight having refrained from voting. But, as in the other three cases, the "bean" of 1862 excluded him. His case led to the visitation, and the quashing of the bye-law. These facts prove that it was not the ballot alone that prevented Catholic candidates from obtaining the votes of their Protestant colleagues. We now come to the elections held since the decision in 1870, and we find, under open voting, that Dr. Cryan, Professor in the Catholic University, was elected; while one of the above four Catholics who had obtained a majority under the ballot—a highly esteemed and distinguished practitioner—was left in a minority in open voting.

THE ACTION OF DRUGS.

VIII.

THE Committee next proceed to ascertain by experiment the antagonism between theine and meconate of morphia, the physiological action of theine having been determined by Dr. Alexander Bennett, and they now choose rabbits and cats as subjects for experiment, having observed that the symptoms produced by the action of theine on these animals, more especially the latter, were very characteristic. That the symptoms are more marked in the cat than the rabbit is what we should naturally expect, and is a reason why we should choose animals high in the scale, as cats, dogs, or horses, when we desire to ascertain the full physiological action of a drug, the more so when we have to deal with drugs that influence powerfully the nervous system; for if the experimenters had contented themselves with rabbits as subjects, they would only have ascertained that the fatal dose of theine for a rabbit of from 3 lbs. 4 ozs. to 3 lbs. 2½ ozs., is between 5¼ to 5½ grains, and that 5 grains given to a rabbit weighing 3 lbs. 4 ozs. caused marked paralysis and twitches; but having also used cats, they found that the same quantity administered to a cat of 4 lbs. 10 ozs. produced great excitement and slight paralysis, although the minimum fatal dose is nearly the same, viz.—5½ grains for a cat of 5 lbs. This difference is noted by the experimenters, for they say:—

The chief point of difference between the action of theine on the cat and on the rabbit is the intense excitement produced in the former. This is well illustrated by the following experiment, No. 473.

Experiment 473. A male cat, weighing 4 lbs. 9 oz., had six grains of theine injected under the skin of the back. For five minutes, nothing was observed. At the end of this period it began to move backwards and forwards, and the excitement gradually increased until the close of fifteen minutes after the administration of the drug, when it seemed to be frantic. These fits of intense cerebral excite-

ment afterwards occurred at intervals of two or three minutes. Between them the animal lay quiet. It appeared to be extremely susceptible to irritation. A stick brought near it was immediately bitten. Salivation became very profuse. Twelve minutes after the dose had been given, the cat had difficulty in moving its posterior extremities. This difficulty gradually passed into complete paraplegia. Thirty minutes after, it could not move the hinder part of its body, but its senses were very acute. The animal noticed every movement made near it, and it tried to bite. The paralysis gradually invaded the fore extremities also, and the cat was unable to sit up. It lay with its head slightly raised, but still there was the same acuteness of the senses of hearing and vision, and it was easily irritated. It remained in this condition for an hour and a half, when, after two very severe clonic spasms, it died.

The narrative of the above experiment indicates intense cerebral excitement associated with gradual loss of the functions of the spinal cord.

Having thus determined the minimum fatal dose of theine for a rabbit and a cat, the next point was to ascertain the minimum fatal dose of meconate of morphia for a cat, and for this purpose ten experiments were made, and the experiments, as reported in Table 55, show that for an average-sized cat a dose of $1\frac{1}{2}$ grains of meconate of morphia is nearly fatal, while a dose of $1\frac{3}{4}$ grains is certainly so. The physiological effects are similar to those already recorded as occurring in the dog, but in addition, it was observed that small doses produced *dryness of mouth*, but large doses produced *salivation* (italics ours). This is a point of great interest, for we have already (*vide* MEDICAL PRESS, Article V., page 505) called attention to the dual action of drugs—in the case of atropia—and there is little doubt that all drugs possess this dual action; and no opportunity should be neglected of determining the peculiar range of symptoms produced by large and small doses, and more stress should be laid on this much-neglected point. The experiments now recorded go far to prove that it is not sufficient to say that such a drug salivates, or the reverse, but that it should be determined in all cases what dose produces salivation and what dose tends to produce opposite effects, and thus our knowledge of the therapeutic power of drugs would be increased—a consummation most devoutly to be wished. We are glad to note that recent experimenters and writers on therapeutics are commencing to direct attention to this point, and also to the immense importance of having an exact knowledge of the physiological action of drugs before determining their therapeutic uses. We have from time to time, in these articles, commented on these points, as we consider that the Report of the Committee should not be merely read as a record of curious experiments to be wondered at, but that wherever possible, practical use should be made of it in modifying our present too haphazard mode of using drugs. Moreover, these experiments should, and must be, of great importance to the scientific therapist, and they will also serve as guides to future researchers.

We now return to the report of the antagonism between theine and morphia—the minimum fatal dose of morphia having been determined—and we observe that the Committee state the conclusions to be drawn from these experiments to be as follows:—

1. There appeared to be an antagonistic action between the two substances, inasmuch as the symptoms produced by either were considerably modified, but life was not saved; and
2. The meconate of morphia delayed

the appearance of the convulsions characteristic of the action of theine, while, on the other hand, the theine did not appear to affect in a marked way the action of the meconate of morphia. As the latter conclusion did not appear to be sufficiently obvious at this stage of the inquiry, the question was re-examined in a second set of experiments some time afterwards. In this second set of experiments, smaller doses of theine were given.

The result of the second set of experiments with smaller doses of theine showed without doubt that theine influences the physiological action of meconate of morphia, because, after a dose of that drug, which alone would produce coma, if theine be also introduced, it is followed by a period of cerebral excitement. Although the limits of the antagonistic action are narrow, it will be seen—(1) that while a cat may recover from the effects of a dose of $1\frac{1}{2}$ grains of meconate of morphia given alone, it will rarely recover (Experiment 494) from the effects of a dose of 2 grains, even should the effects of the latter dose be modified by those following the introduction of 4 or 5 grains of theine; (2) that in three cases (Nos. 501, 504, and 505) the animals recovered from the effects of $1\frac{1}{4}$ grains of meconate of morphia and 4 to 5 grains of theine, while they died when the same dose of meconate of morphia was administered eight days afterwards; (3) that when the dose of theine was increased beyond 5 grains, the animals invariably died apparently from the effects of the theine (Experiments 488, 489, 490). The important result, however, is shown that fatal doses of meconate of morphia ($1\frac{1}{2}$ and even 2 grains) may be completely antagonised by theine.

Afterwards, a few experiments were made on rabbits as to the antagonism between morphia and theine, and the conclusion arrived at was that—

The experiments on rabbits were considered so unsatisfactory, that they were not prosecuted further, because it was evident that in this animal meconate of morphia did not produce effects comparable to those following the action of the substance in carnivorous animals. The specific action of salts of morphia in rabbits is to produce, in addition to a stupor not nearly so profound as in carnivorous animals like the dog or cat, convulsions of an epileptiform character. Theine produces somewhat similar effects in rabbits. At the same time, it was observed that the drowsy appearance following soon after the exhibition of meconate of morphia in rabbits was much less marked in those instances in which theine was also administered.

Here again we have another proof of the necessity of not being satisfied with the results of experiments on rabbits; and we only wish that the experiments with Calabar bean, chloral, atropia, &c., had not been limited to rabbits, as we should then feel more satisfied with the conclusions arrived at by the Committee. Still, we fully appreciate the value of their labours, and are only too pleased to observe that their attention has been drawn to the different symptoms produced in various animals. We also refer our readers to our former remarks on this subject in previous articles.

In reference to the antagonism between caffeine and meconate of morphia, the report reads thus:—

This question was investigated in exactly the same way as had been done with theine and meconate of morphia, and the results were the same. As has been shown by Dr. Alexander Bennett, the physiological actions of theine and caffeine are so similar as to make it impossible to distinguish the one from the other. The following experiments were made on cats, because, as has been stated above,

experiments on rabbits with these drugs were not considered satisfactory. As the experiments were precisely similar to those made as to the action between theine and meconate of morphia, it is not necessary to give them in detail.

The experiments showed the minimum fatal dose of caffeine for a cat of about 5 lbs. to be near 6 grains. The effects produced were similar to those following the introduction of theine, and an analysis of Table 59 shows the very important result that in three cases (Nos. 529, 535, and 540) the animals recovered after a dose of $1\frac{1}{2}$ grains of meconate of morphia and 4 grains of caffeine, while they died after the administration, eight days after the first experiment, of $1\frac{1}{2}$ grains of meconate of morphia alone. On the other hand, in two instances (Nos. 530 and 531) the animals survived the crucial experiment. When the dose of meconate of morphia was less than $1\frac{1}{2}$ grains (as in Nos. 536, 541, 542, 543, and 544), the animals survived both the simultaneous action of the drugs and the crucial experiment. In these cases, it is fair to suppose that a dose of $1\frac{1}{2}$ grains was not a fatal dose for these particular animals. From these facts, it seems reasonable to believe that caffeine antagonises the action of meconate of morphia by modifying the symptoms, and even to the extent, in certain instances, of saving life, but that the antagonism is limited. On the one hand, the animal may die from the effects of too large a dose of caffeine, and, on the other, from the effects of too large a dose of meconate of morphia; but there is a point between the two actions where the physiological effect is such that life may be saved from doses which would otherwise prove fatal.

The experiments with guaranine and morphia recorded in Table 60 led the Committee to conclude—

There could be no doubt, from these experiments, that guaranine modified to a considerable degree the physiological action of meconate of morphia. The animal in experiment No. 547 recovered after a simultaneous dose of two-thirds of a grain of meconate of morphia and three grains of guaranine; but in experiment No. 548, the same animal, seven days afterwards, recovered from a dose of two-thirds of a grain of meconate of morphia administered alone. This showed that two-thirds of a grain of meconate of morphia for this particular animal was not a fatal dose; but the symptoms were considerably different in the two instances. In the first experiment, No. 547, in which both drugs were given, there was excitement with no stupor; while in the second experiment, No. 548, in which the narcotic was given alone, there was no excitement, but deep stupor approaching to coma.

The Committee next proceed to ascertain if any antagonism exists between infusion of tea and meconate of morphia, having, as we have already seen, determined the extent of the antagonism between theine and morphia; but now the experimenters found so many difficulties attending the method of inquiry, and the results obtained were so unsatisfactory, that they were compelled to abandon this line of experiment. They, however, made five experiments on dogs, using a strong extract made from 3 oz of best green tea, dissolving the extract in warm water, and injecting this solution into the stomach of the animal by means of a stomach-pump; but they found that—

1. The tea was frequently vomited within so short a period after its introduction as not to afford time for the exercise of any antagonistic action to the effects of the meconate of morphia, which it might be supposed to possess. 2. The animal was so much excited by the

operation of the introduction of the stomach-pump, that it was very difficult afterwards to say how far the effects were produced by the operation, and how far by the introduction of the tea. As a general example of the kind of action, the following two experiments may be quoted.

Experiment 551.—A mongrel terrier dog, weighing 24 lbs., had one grain of meconate of morphia in forty minims of warm water injected subcutaneously under the skin of the back. The usual effects were produced of slight nausea, restlessness, stupor, passing into a semi-comatose condition, in which latter state the animal continued for a period of six hours. It then slowly recovered.

Experiment 552.—The same dog, five days afterwards, was now found to weigh 23 lbs. All the effects of the meconate of morphia had disappeared. One grain of meconate of morphia in forty minims of warm water was subcutaneously injected under the skin of the back. Immediately thereafter, eight ounces of a strong aqueous solution of the extract of tea were injected into the stomach. Five minutes afterwards this was rejected by vomiting. At the end of another period of five minutes, another injection of eight ounces of tea was given. Part of this was almost immediately rejected. The animal was now very restless and irritable, and it was by no means easy to make any observations of its condition, as it readily attempted to bite. Ten minutes after the last injection of tea, a third dose of eight ounces was given. This was retained. The dog was now much excited. It ran up and down in the laboratory, with a staggering gait. Occasionally it would lie down for a few moments, and again rise to begin its perambulations. There was no stupor strictly speaking, but it had a dull heavy expression of eye. There was no coma. It urinated freely and frequently. There was also diarrhœa attended apparently by tenesmus. The dog continued in this condition for nearly six hours. At the end of this time it began slowly to recover. The most evident effect in this experiment was the intense restlessness of the animal. There could be little doubt that the tea counteracted the physiological action of the meconate of morphia.

Thus, at present, the extent of the antagonism between infusion of tea and morphia is undecided; but as Professor Hughes Bennett observes, further experiments should be made both on animals and man. Nevertheless, some knowledge may be gleaned from these few experiments, unsuccessful as they have been; for example, it is stated that the dog used in Experiment 551 recovered after a dose of *one grain* of meconate of morphia: this we would naturally expect, when we remember that Professor Bennett has recorded that a dog weighing 12 lbs. recovered after taking *two grains* (see *British Medical Journal*, page 582); and as the animal used in the present case weighed 24 lbs., we could hardly expect it to succumb to a dose of only *one grain*, that is, if weight has as great an influence over the effect produced as the experimenters seem to believe; moreover, if the same dog five days afterwards (then weighing 23 lbs.) had failed to recover from the second dose of morphia, viz., one grain, we would have the more reason to be surprised, or we might even feel inclined to attribute the fatal termination (if such had occurred) to the action of the tea; but the report states that this animal (weighing 23 lbs.) recovered after a dose of one grain of meconate of morphia and twenty-four ounces of warm aqueous solution of extract of tea, given in three separate doses of eight ounces; and referring our readers to the experiments quoted above, they will observe the difference in symptoms produced when morphia is given alone and when given with the tea. It is not quite clear to us, however, that the modification of the

symptoms was not due in a great extent to the rapid elimination of the morphia by the bowels and kidneys, as the animal urinated freely and frequently, and diarrhoea was also present, effects not usually produced when morphia is given alone. Nevertheless it is no doubt true that the physiological action of tea is antagonistic to that of morphia; the difficulty, however, is to introduce the tea into the system (and not only into the stomach) rapidly enough to counteract the morphia. We must remember that in Experiment 552, while the morphia was injected subcutaneously, and would commence to act almost immediately, the tea was only introduced into the stomach, and had to be absorbed first before its physiological action on the system could be produced in any marked degree; and in addition, the solution of tea was introduced into a viscus already so much irritated that nausea and vomiting was present; but if, as in the case detailed by Professor Sewell, of Quebec, and quoted by Professor Bennett, the solution of tea had been introduced *per rectum*, we might have expected a more satisfactory result.

Before concluding our observations on this portion of the report, we cannot abstain from calling attention to Table 61. In Experiment 553 a dog weighing 26 lbs. receives one grain and a-half of meconate of morphia, and twenty-four ounces of solution of extract of tea: the tea is rejected by vomiting, stupor and coma follow, and death in three hours. In Experiment 554, a dog weighing 24 lbs. receives one grain of the morphia salt, and twenty ounces of the tea solution, and death follows in 2½ hours. And lastly, in Experiment 555, the dog weighed 26 lbs., received 2/3rds of a grain of morphia and sixteen ounces of tea, yet it died in 8 hours. These results are peculiar when we bear in mind that the dog used in Experiment 375, weighing only 12 lbs., recovered after a dose of *two grains*. Such being the case, the cause of these discrepancies should be determined before endeavouring to fix the minimum fatal dose.

In reference to the antagonism between meconate of morphia and strong decoction of coffee the Committee state that—

It was found that a strong decoction of coffee was rejected so quickly by the stomach, while the animal was affected by meconate of morphia, as to take away all hope of exercising any influence on the physiological action of that drug.

Notes on Current Topics.

A Homœopathic Surgical Miracle.

MR. BEEBE, of Chicago, is one of the brightest lights of homœopathic surgery in America, and the *Chicago Medical Investigator* is a standard exponent of homœopathic literature. We read, says the *Pacific Medical Journal*, in the said journal, that Dr. Beebe "has recently performed another unique operation. He was telegraphed for to operate on a case of strangulated inguinal hernia. When he arrived, the local doctor had succeeded in reducing it with hot fomentations. But now arose a difficulty. The bowel was gangrenous, and blood oozed from the anus. No passage could be obtained. Adhesion had

closed the intestine. Dr. Beebe concluded upon abdominal section. The closed gut was found; the walls were intact, and by manipulating the contents, the adhesion was broken up, and a passage effected. The man is now well."

The story is told word for word as we give it. What a precious lot of fools, says the *Pacific Journal*, the readers of the *Investigator* must be, to believe such stuff! It asks the question—Can anyone inform us why homœopathic doctors and their friends complain so continuously and so piteously, because regular physicians refuse to consult with them, or admit them into their associations, whilst at the same time they constantly denounce regular practitioners in mass, as poisoners, butchers, murderers, and all that? If the "allopaths" (so called) are so blind, bigoted, and deluded, and if their practice is so fraught with failure and death, why should the disciples of Hahnemann everlastingly long for companionship with them, and keep up a perpetual cry of complaint?

An Authenticated Centenarian.

THE accounts of the great ages of some persons which find their way almost daily into the newspapers are looked upon with a great deal of scepticism by many who are competent to form an opinion. The *Philadelphia Medical Times* records, however, the death of a person, respecting whose age there can be little doubt, and, if true, the endurance of life and health in him was very remarkable.

"George Labar was born in the autumn of 1763, one hundred and eleven years ago, at Mount Bethel, where his baptismal register still exists, his grandfather settling in Pennsylvania in 1730, a fugitive from religious persecution. Nearly seventy years ago he accompanied his parents in their emigration to Ohio, but only remained with them a few days, and returned home.

"George Labar had never been sick but three times in his life: once with yellow fever, once with camp fever, and once with typhoid fever. He used tobacco very freely all his life, both smoking and chewing, but was very moderate in his use of liquors of all kinds. He took daily exercise in the woods, among which he had grown up, felling trees and chopping railroad-ties up to within the last two or three years. It is recorded of him that in 1869, when one hundred and seven years old, he felled trees and peeled three wagon-loads of bark, which one of his youngest sons, a young chap of sixty, hauled to market for him.

"His oldest son was born in 1791, and married, at twenty-one, a girl of thirteen! Their oldest child is now sixty, and is only fifteen years younger than his mother. In 1870, George Labar had living a sister aged eighty-six, another sister aged ninety-two, and a brother, in Canada, aged ninety-eight, a brisk old boy."

Parenchymatous Nephritis.

M. CHARCOT (*Le Progrès Méd.*, December 5) gives the following microscopic appearance as belonging to this form of kidney. The organ is large, and often has a weight and volume double that of the normal. The colour is white, sometimes dull white, more or less like ivory; sometimes it is of a yellowish hue, more or less marked. This colouration

belongs exclusively to the cortical part of the kidney. We perceive it at the surface of the organ, after removing the capsule, which is not at all adherent; at the same time we recognise that this surface is absolutely smooth, and not presenting projections or cysts, as in the granular kidney. We never see in it depressions other than those which separate the great natural lobes, and even the lobular structure of the kidney, as it is marked in the normal condition by vessels, is here effaced; the vessels are only seen here and there like rare disseminated stains. On sections being made we also recognise the considerable swelling of the cortical substance and rarity of the vascular striæ.

The medullary substance does not present any appreciable alteration; its colour, which is generally normal, contrasts with that of the cortical substance.

Histological Appearances.—When this form exists in all its purity, the alterations are localised almost exclusively in the convoluted tubes and the epithelium, which present modifications so slight that they only differ by shade from the normal conditions, and that an exercised eye is required to be sure of them.

For a long time we notice nothing more than a dull swelling of the epithelium. The cells are darker than in the natural condition (on account of the presence of a great number of fine granulations), and are at the same time more voluminous and swollen, so that the diameter of the tubuli is narrowed; often also, but not constantly, the free part of the tubes is completely obliterated by fibrinous cylinders. There exists no appreciable alteration in the connective tissue, or in the vessels.

You see, then, that we have here to do only with simple shades or kinds of alteration of the normal conditions; for you have not forgotten how, in these conditions, in the living animal as well as in man in health, the glandular epithelium of the twisted tubes presents a dusky hue and numerous granulations, and that the diameter of the tubes is reduced to a very small affair. It is not astonishing, then, that certain authors, and Gairdner in particular—to whom is due one of the first works on the subject—should have been led to declare that the results of histological investigations are in such cases, as may be said, negative. Nevertheless, the swelling of the epithelial elements is incontestable, and it is to that that we must attribute for the most part the augmented volume of the organ.

Besides the opacity of the epithelial cells, we also notice, as characteristic of parenchymatous nephritis, a marked change in the tubuli contorti, and varicosities of their external contour; and a certain degree, rather difficult to appreciate, I think, of thickening of the tunica propria of the tubes.

The tumefaction of the epithelium may be the sole alteration met with, even when death has arrived long (six months or a year) after the commencement, but frequently also it complicates itself by a true infiltration of fatty nature of the cell elements. The latter contain, besides proteinic granulations soluble in acetic acid, more or less voluminous granulations, which resist acetic acid, and are dissolved in ether. The tubuli whose epithelium is thus swollen appears under a slight magnifier quite black and opaque; these are especially the tubuli contorti, but also the straight tubes, which present these modifications, which differ from the normal. Sometimes the fatty degeneration

is uniformly spread, and to the naked eye the general aspect of the kidney is only slightly modified. It presents only a yellow tinge, like buffalo's skin, which replaces the pale tint, or ivory hue, but it remains voluminous and smooth on the surface, without presenting granulations. This condition is sometimes designated under the name of the large fatty kidney.

At other times the fatty degeneration affects only here and there some groups of the tubuli contorti, the intermediate groups remaining in the first degree of the alteration. These groups of tubuli become fatty, appear opaque relatively to others, and form even sometimes small swellings, appreciable not only at the surface of the kidney, but also on sections, in the thickness of the cortical substance. These granulations differ, you see, from those we have studied on the kidney affected with interstitial nephritis; for the latter only exist at the surface, and are produced by the persistence of medullary rays of each lobule. The naked eye appearance corresponding to this alteration has been depicted by Bright in his third plate, by Rayer in his eighth; it is the fourth form described by this author. Johnson calls the kidneys thus altered fatty granular kidneys.

New Sign of Death.

DR. MONTEVERDI, of Cremona, recommends what he calls an "easy, prompt, and certain" method of demonstrating the reality of death in man, which is recapitulated in the *Philadelphia Reporter*. It consists in the observation of a spot produced by the injection of a drop or two of ammonia beneath the skin. If the man be living, the spot produced by such injection is always of a more or less vinous red, whilst, if he be dead, the colour is scarcely different from that of the skin itself, or, at least, has no purple tint. The solution of ammonia injected should have a strong odour of the gas, and a specific gravity of 0.92. If the individual be living, no bad effects are produced, beyond a burning pain which lasts for a short time, and the reddish tint appears almost immediately. The spot appears to be due to the action of the ammonia on the blood.

A New Variety of Senna.

THE *Pharmaceutical Journal* states that there is now in London a very large quantity of a drug which is being offered as fine senna. It may be distinguished from officinal senna by the peculiar arrangement of the veins of the leaf. Instead of having one central vein, with all the others branching from it, as in senna, the leaves of this variety have two or more prominent veins starting from the centre of the base of the leaf, and these are repeatedly forked in an almost parallel manner. The leaves appear to belong to a species of *Cassia*, and may therefore possess purgative properties.

At the meetings of both vestry and guardians of St. Pancras, last week, resolutions were adopted to appeal to the President of the Local Government Board not to sanction the plans for the Hampstead Hospital until Parliament had expressed an opinion on the subject. The latter board also determined to enforce the penal clauses of the Vaccination Act.

Physicians' Sacrifices.

PROFESSOR O. W. HOLMES, of Harvard University, U. S., in an address at the opening of a new Medical College, quotes a passage from the author of "Modern Christianity a Civilised Heathenism." It runs as follows: "Men are pleased to call you reverend," he says, addressing the English clergy, "but if such a title belongs to any profession on this earth, it belongs, not to the parson, but to the doctor. He it is who, in some degree at least, is making himself Christ to the suffering and sorrowing among mankind. He it is who turns out of his bed at midnight to cool the poor man's burning lips, or succour a woman with the tenderest efforts of his skill, who can never pay him sixpence for his trouble, whether her infant lives or not. What you do cheerfully enough once in a way, he does as a matter of business all day long. Your work is baby's work compared to his."

Mortality Statistics of Labour.

DR. WELLINGTON (*Boston Med. and Surg. Reporter*, Dec. 3, 1874) referred to this point in the Boston Obstetrical Society. In his own cases, Dr. Wellington had a record of 634 labours and 10 deaths: of the latter, one from valvular disease of heart, three from pyæmia, two from brain disease (probably apoplexy), three from consumption, and one from puerperal mania. Excluding the three cases of phthisis and one of valvular disease of the heart, as not being properly puerperal, there were six, or one in 105 occurring within four weeks after delivery. He never allowed a woman to get up before two weeks, if possible.

Cauterization of the Uterus.

DR. WILLIAM GILLESPIE (says the *American Medical Weekly*) directs to take an ordinary sponge tent, coat it with bees' wax, and then roll it for some time in powdered nitrate of silver, which will sink into and adhere to the wax. Then, with a suitable speculum, carry the tent through the cervix, and, if desirable, to the fundus, and let it remain twenty-four hours. No remedy in his hands has done more good in a short time in chronic inflammation, enlargement, or ulceration of the os and cervix, and he has never known any unpleasant results occur from its use.

Treatment of Nævi by Vaccination.

DR. ROGAINE (*Jahresbericht d. Ges. Med.*, 1874) reports seven cases of erectile nævi cured by vaccination. The operation may be performed at the circumference or on the surface of the tumour. It is important that the points of insertion be made as far apart as possible, and care must be taken not to let blood wash away the vaccine matter. No size of nævus is any contra-indication to the operation.

Alopecia Areata.

DR. MELASSES (*Arch. de Physio.*, May, 1874) examined the scales scratched from the epidermis from bald patches in this disease, where the fungoid spores were found the most early. Having removed grease by ether or absolute alcohol, he found very small spherical spores, and no

mycelium. The fungus occupies the most superficial parts of the horny layer of the epidermis, and is only accidentally met with on the hairs.

The Medical Microscopical Society.

At the monthly meeting of the Medical Microscopical Society of London, held on Friday last, at the Royal Westminster Ophthalmic Hospital, Dr. J. Frank Payne, B.A. Oxon., M.B., F.R.C.P. Lond., was unanimously elected President of the Society in succession to Mr. Jabez Hogg, who has filled the chair for the past two years. At the same meeting, on the motion of Mr. Needham, it was resolved to try the experiment of publishing a Year-Book of the Transactions of the Society.

Ferruginous Wine with Cinchona, and Cinchona Wine, prepared by F. Arout, Rue Constantine, Paris.

THESE are most agreeable and elegant preparations, and are sure to meet with a hearty reception by all patients required to take the drugs they contain in a pleasant form. The ferruginous wine with cinchona is a most pleasant medicine—one of the most pleasant we have ever tasted—and we can heartily recommend it to the notice of the profession. The French have always been noted for the elegance of their pharmaceutical preparations, and these wines fully keep up the ancient renown of Paris.

Election of a Professor of Midwifery in the Irish College of Surgeons.

THE election of a successor to Dr. Sawyer took place on Friday last, when the Council and a small number of the Fellows assembled for the purpose of witnessing the election. The candidates who had lodged applications for the office were—Dr. John Cronyn, Dr. William Roe, Dr. Halahan, Dr. Rutherford Kirkpatrick, Dr. Thomas More Madden, Dr. Arthur Hill Ringland, and Dr. Isdell. As enjoined by the Charter, seven of the Council were selected by lot to elect, the gentlemen on whom the lot fell on this occasion being—the President, Mr. Tufnell, the Vice-President, Mr. Edward Hamilton, Dr. McDowell, Dr. Smyly, Dr. Chaplin, and Mr. Butcher.

After deliberation in secret, the electors returned to the board-room and declared that they had chosen Dr. John Cronyn.

Dr. Cronyn is a well-known and popular obstetrician. He served as Assistant-Physician to the Rotundo Hospital, and has been named as a probable candidate for the *Masterhip* on the retirement of the present Master. He has acted for some years as Examiner in Midwifery in the College, and was last year appointed by the Council to deliver the lectures on midwifery during the temporary illness of Dr. Sawyer.

Upon the Presence of Phosphide of Sulphur in some Cases of Break-down of the Nervous System.

"M. JULES LE FORT does not consider that the garlic-like odour and phosphorescence notable in putrefaction are due to the disengagement of phosphoreted and sulphureted hydrogen; but to the production of phosphide of sulphur, and that the latter is the essential element of phosphorescence. This substance, which forms sponta-

neously in animal matter undergoing decomposition, may perhaps be the cause of the symptoms produced by the ingestion of preserved meats slightly tainted by decomposition, like salt fish, pork, &c."—*Paris Journal of Medicine.*

Sudden disintegration of new tissue, when the blood is not perfectly oxygenated, may cause the presence in it of the "phosphide of sulphur," remarkable for its garlic-like odour and its property of producing putrefaction. Sulphur, to be sure, does not exist in nerve-tissue, but it does in muscle, and many articles of food. This phosphide of sulphur, by thorough oxygenation, would be converted into harmless phosphates and sulphates. However, it is sometimes got rid of by colliquative diarrhoea. This assumption or hypothesis will explain the foetid emanation from the persons of those suffering from a break-down of the nervous system and some other states characterised by emotional susceptibility. Treatment based upon this assumption will consist in economy of vital force. Every act of life, for every mortal, involves death, that is to say, for every thought of our brain, for every movement of our limbs, an atom, or atoms, of nervous or muscular tissue dies, it is swept away by the current of the blood, which simultaneously deposits the elements of new tissue, and is, after having served any further useful purpose to which it can be applied in the system, eliminated therefrom. That is health. But in some states of the nervous system aptly characterised by the familiar term a break-down, for every one atom of nerve-tissue that dies in health, as a result of exertion of mind or body, or any passion or emotion, three or four atoms die, and this excessive disintegration of tissue, unless the *débris* is removed by increased oxidation, or eliminated somehow by the excretory organs, will poison the healthy current of the blood, hinder repair of nervous and all other tissues (the new tissues bearing about the same likeness to the old that the cicatrix of a burn does to true skin) and convert Youth, which is Victory into Age, which is Defeat.

Individuals who start in life with a small capital of vital force, and they are many, must economise if they would avoid a physiological bankruptcy, or break-down; that is to say, excessive work of mind or body, all causes of excessive worry, excess in nervous or alcoholic stimulants (it is absurd to say these lessen waste, they only lessen elimination), all other forms of dissipation. Any one of the above-named causes will be likely to develop inherent weakness, but a combination of many, or all (rarely met with, it is true), would break down a physiological millionaire. After doing your utmost to check the excessive production of phosphide of sulphur by lessening waste, expedite its removal by doing everything to favour oxidation, and so convert it into harmless phosphates and sulphates. Fresh air, light clothing, Turkish baths meet this indication tolerably well. As civilisation advances, burdens are growing heavier, and backs are growing weaker; consequently, break-downs are of constant occurrence. Therapeutics cannot lighten the former, though, as sanitary science advances, essays will be made even in this direction; but it can, in some degree, strengthen the latter, and the Turkish bath is the remedy *par excellence* for this object. Total break-downs.

are, perhaps, as incurable as phthisis, to which they bear an analogy; but in the majority of cases an approximation to a cure may be effected by removing the exciting cause, of whatever kind it may be, and applying the ordinary rules of that rare gift—common sense, and of hygiene. These too often, however, conflict with the obligations or habits of the patient, and contending emotions, of whatever nature, are precisely what ensure a break-down. The last words of Esquirol, the great master of mental science, to his disciples, were, "Cultivate peace," and in that peace is contained "Good will towards men."

Hospitals for Isolation and Treatment of Zymotic Diseases.

At the meeting of the Sanitary Conference in Birmingham, last week, Dr. Pritchett, medical officer of health of Huddersfield, read a paper on the above subject, which was full of common-sense suggestions and remarks. He pointed out that it was the imperative duty of every sanitary authority to provide means for instant detection and isolation of cases of zymotic disease, inasmuch as not only might persons be exposed to contagion, but these might infect others in a variety of modes, each of these secondary cases forming centres from which an infinite number of radiations of infection might extend. It was well known that infectious diseases first appeared and abounded in the houses of the poor, who were either of migratory habits or who mingled with those who were, each class living in overcrowded and badly ventilated courts or lodging-houses. Epidemic infectious disease meant suffering, expense, loss of money, permanent disability in many cases, death in as many more, and pauperism of families whose heads had been removed by death. From the latter class paupers were bred, who for generations lived on the rates or filled the gaols. Any means, therefore, of preventing sickness and death amongst the poor would be a saving to the public purse. The chief means to this end, he believed, was the provision of sufficient inspection, and of special hospitals into which cases of zymotic disease might be taken on the first appearance of any outbreak, not only in cities and towns, but also in villages, if distant from a large town; for it was a matter of experience that fever had often been introduced into the town from a neighbouring village, where it had been generated by a condition of things contrary to all sanitary laws. Isolated fever hospitals should be in number according to the size of the town, so that they be not crowded and the officials overtaxed, as well as that the patients might not have to endure the distress of a long journey. No paupers should be allowed to mix with ordinary patients, who were, or ought to be, ratepayers; for the honest though poor working man considered it a stigma upon his character to be associated with paupers. Paupers should go to the workhouse fever wards. In many places it would be found an advantage to provide distinct wards for the accommodation of those who would like to pay for privacy and special nursing. Having recounted the success which had attended the isolation of infectious disease in Huddersfield—small-pox epidemics having been arrested five times—Dr. Pritchett concluded by begging all medical officers of health not to let their sanitary authorities

rest until an area and a refuge for the fever-stricken had been provided. He urged sanitary authorities to think not of economy in the matter, as they would find that such lazarettos were the cheapest things they could buy with the ratepayers' money. Ladies who wished for benevolent work would find a great field for intelligent nursing in the hospitals, there being more satisfaction and less labour in it than in the duties of the governess, or a companion to some one who would probably have more whims than a fever patient.

PROFESSOR HUXLEY has written a vigorous essay on "Haeckel's Development of Man" in the *Academy*.

TWENTY cases of scurvy have been admitted into the Seamen's Hospital during the past year.

MR. EDMUND STEVENS, late of Farnham, Surrey, has bequeathed to the Royal Surrey County Hospital a legacy of £500.

IN consequence of the resignation of the Duke of Montrose, the Chancellorship in the University of Glasgow becomes vacant. Sir Wm. Stirling Maxwell and Lord Moncrieff are announced as likely to contest the chair.

THE Hunterian oration this year will be delivered at the Royal College of Surgeons of London on Saturday, Feb. 13, by Mr. F. Le Gros Clark, President of the College.

A WARNING to doctors is issued by the *San Francisco News Letter*, which announces its intention in future of publishing after each death-notice the name of the attending physician.

IN addition to a gift of £25 by the Bishop of London, from the fund left with his lordship by the Emperor of Russia on his last visit to England, University College Hospital has received a further donation of £10.

BY the death of Dr. Robert Adams, a vacancy is created in the Council of the Irish College of Surgeons. Dr. Henry Gray Croly has declared his candidature. Dr. Croly is a Licentiate of eighteen years' standing, and a Fellow of twelve years', and is Senior Surgeon of the City of Dublin Hospital. He formerly held a seat on the Council, but retired from it in consequence of temporary ill-health.

PROFESSOR ERASMUS WILSON will commence his course of six lectures on "Dermatology" at the College of Surgeons of England on Monday, the 1st of February next.

Professor W. K. Parker will deliver a course of eighteen lectures on "The Structure and Development of the Skull," in continuation of his course of last year, commencing on Monday, the 15th of February next.

In June next Professor Henry Lee, and Mr. William Turner, Professor of Anatomy in the University of Edinburgh, will complete the lectures for the present year, the former by a course of six lectures on "Syphilis, and on some Local Diseases affecting principally the

Organs of Generation," and the latter by three lectures on "The Comparative Anatomy of the Placenta."

THE next meeting of the London Pharmaceutical Society will be held on Feb. 3, at eight o'clock. A discussion on "The Construction of an International Pharmacopœia, from the Pharmacist's Point of View," will be introduced by Mr. Sutton, one of the delegates to the recent International Pharmaceutical Congress.

Literature.

THE (NEW YORK) PSYCHOLOGICAL AND MEDICO-LEGAL JOURNAL.

OCTOBER AND NOVEMBER, 1874.

We doubt if it would not be better for the students of psychology in the United States if the editors of the journal devoted to their specialty were to adopt the plan of a quarterly instead of a monthly publication. The United Kingdom contains many ardent students of mental science, and our public asylums furnish rich materials for observation; but a quarterly issue of the *Journal of Mental Science* is found sufficient for all purposes, and it presents this great advantage, that papers submitted for professional perusal can, in many cases, be given in a completed form, either for study or for review. There can be no second opinion as to the ability with which the *American Psychological Journal* is conducted; it is conspicuous in every number of the publication. Some of the best papers are not strictly confined to the subject of insanity, but all are of remarkable merit.

The October number opens with a paper on "Certain Nervous Affections of the Throat," by Dr. Clinton Wagner, who shows his thorough acquaintance with the latest laryngoscopic researches of the day. Next follows a paper by Dr. William A. Hammond, the editor, upon "The Influence of the Disulphate of Quinine over the Intracranial Circulation." This is the most valuable contribution of the number. Dr. Hammond gives the details of a series of carefully-planned experiments, carried out in his own person, of the effects of quinine upon the cerebral circulation, and he proves to demonstration that this drug causes hyperæmia and congestion of the cerebral vessels. The constant effects produced were redness of the face, increased action of the carotid and temporal arteries, suffusion of the eyes, heat of head, congestion of the retina and of the tympanum, and he considers that quinine has a tendency to produce, not only temporary difficulty of hearing, but in some cases *permanent deafness*. Dr. Hammond's observations lead him to doubt the effect credited to quinine of reducing enlarged spleens, and he attributes the reduction quoted in Pirry's experiments, where an alcoholic solution was thrown directly into the spleen, to the effect of the alcohol rather than that of the alkaloid. He concludes that quinine should never be administered in cases of active cerebral congestion, but that it may with benefit be given in cerebral anæmia. Dr. Hammond's paper deserves attentive study. "Insanity, its Treatment, Ancient and Modern," is an interesting address by Dr. Kellogg, and is as remarkable for its literary ability as for the thorough acquaintance with the subject shown by the author.

Dr. James I. O'Dea contributes a remarkable paper upon "The Philosophy of Suicide," in which he shows a profound acquaintance with the literature of the subject. He traces the influence of the academic speculations of the Greek and Roman philosophers upon the practice of suicide, and traces the destructive influence of the corrupt social life of imperial Rome upon the value set on human life.

A masterly historical review of the subject closes the October contribution of this writer, and in the November number he proceeds to the study of the general causes of suicide. If the ability which marks the early portions of this study of suicide is maintained in future contributions on the same subject, the work of Dr. O'Dea will leave its mark upon the psychology and the literature of the United States.

Turning to the November number, we commend to any of our readers who may wish for a good abstract of the views of the French and German schools upon the subject, a paper upon "Mental Physiology," by Mr. Wallace Wood, of New York. It is written with great clearness, no trifling merit in connection with a very obscure subject.

Both numbers contain, in addition to the original articles to which we have referred, a record of the proceedings of American learned societies, and very able reviews upon contemporary literature.

Correspondence.

THE IRISH COLLEGE OF PHYSICIANS AND THE "DISSENT."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Mythology teaches us to believe that Atlas carried the world on his back; but no amount of respect for myths will enable your readers to believe that Atthill carried the committee of 1867 on his shoulders. This gentleman states that he "drew up the report which was subsequently signed by the other Members of the Committee."

This is true just so far as that Dr. Atthill, as the officer of the College, made a fair copy of the draft report; but he must be well aware that the report in question was the result of a series of compromises between the holders of views of the most antagonistic character. As to the proposal then made for the institution of an order of Members, it is necessary to point out that the Committee fully provided for the interests of Licentiates by proposing that all the existing Licentiates should be at once raised to the new grade of Member.

The proposal under the Draft Charter, it will be at once seen, is of a wholly different nature, as it leaves to the College the definition of the conditions as to fees, &c., under which Licentiates are to be admitted to the grade of Member. That a considerable fee would be imposed is openly avowed by members of the majority, some of whom even contemplate the imposition of a stamp duty.

I call upon the Licentiates to be awake and alive to what is sought to be inflicted upon them. This is, perhaps, for their interests, the most important crisis that the College has ever passed through, and the present opportunity should not be lost for impressing on the Government the necessity of some representation of the Licentiates on the governing body of a corporation to which their fees supply the chief funds. Should any new charter be eventually conceded by the Government, I trust it will contain a provision by which the Licentiates shall be allowed to take some part in the election to the Fellowship. This may be accomplished in a variety of ways: that which I would desire to see carried out would be that Fellows and Licentiates together should all assemble, and all vote openly in the election to Fellowship. If there be one principle better recognised than another in the present day, it is that taxation involves representation, and as the Licentiates supply the funds of the College, I wish to see them directly represented in it. Several Licentiates have done me the honour to communicate with me, and I will feel great pleasure in being the medium of receiving the views of any others of the Licentiates, and aiding in any movement they may set on foot to secure the rights and privileges to which they are justly entitled.

I have the honour to be, Sir,

Faithfully yours,

ROBERT D. LYONS.

8 Merrion Square West, Dublin,
January 10, 1875.

WANTED! A CURE FOR ENURESIS

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Could you or any of the readers of the *MEDICAL PRESS* recommend me any cure for the following case: A strong, healthy young girl, aged 14 years, was attacked about 3 years ago with incontinence of urine during the night, or indeed, whenever she slept, having never showed any symptoms of such disease before. Her father first tried beating her, for he thought it arose from laziness. He also used to call her three and four times a night, but to no purpose. He then consulted me, and I have since tried everything I could think of, or ever heard of, as being used, but without any effect. The girl is extremely strong and hardy, and very callous about it herself. I do not think there can be any malformation, it only occurring during sleep; but I never made any examination, as the parents are greatly against it. She has not yet menstruated, and when she does I am sure she will get better; but in the meantime she is a disgrace to her people and an annoyance to the whole house.

Donegal

I am, yours truly,
M. B.

We are favoured with the following reply from a contributor:—

In answer to M. B., Donegal, as to a cure for enuresis, I venture to suggest a blister, four inches square, being applied to the sacrum, so as to ensure the whole surface being vesicated. After this being done twice, I would follow it up by giving belladonna in such continuous doses as would keep the pupils dilated for a period of three weeks. Special inquiry should be made as to the possibility of worms being present. M. B. might write again at the end of a month.

I am, Sir, yours, &c.,

H. K.

Gleanings.

Chloral as an Application in Gangrene.

M. DEJARDIN-BEAUMETZ communicated to the *Société des Hôpitaux*, at a recent sitting, an account of the case of a young man 18 years of age, who applied for relief for spontaneous gangrene affecting the hand and fore-arm. In order to dissipate the odour and to avoid the danger of septicæmia as far as possible, M. Beaumetz had the affected limb kept constantly in a bath containing one part chloral to five hundred parts water. At the end of eight days the arm was amputated, with a favourable result.

Painful Angiomata.

PROF. TRÉLAT made some remarks on these tumours. Angiomata differ from the tumours called erectile, which should be called cavernous angiomata; the simple variety only contain blood-vessels. Formerly, when a small tumour was painful, it was called a neuroma; but painful neuromata are very rare, while indolent tumours of the nerves are quite common.

Prof. Trélat cited three cases of very painful tumours supposed to be neuromata, but which were afterwards found to be purely vascular; two were subcutaneous, one was submucous and existed at the vaginal orifice. In these three cases ablation was practised, which was followed by cure. Again, a case was cited where severe pain was caused by contact of the median nerve with vicious callus of the bones of the fore-arm; the nervous surface which had been in contact with the bone had become smooth, flattened, and of a ganglionic appearance. Resection of a part of the diseased nerve, resection of the bone, and re-setting the member, were followed by immediate cessation of pain and rapid cure.

Medical News.

Official Report on the Epidemic at Darwin.—Dr. Stephens, of the medical department of the Local Government Board,

who recently visited Darwin, has published his report respecting the outbreak of enteric fever at Darwin and on the sanitary condition of the place. He states that the chief sources of the water supply of the town are situated on neighbouring hills. Up to the present time the intake has been from a small rivulet near Tockholes, two miles distant, and the natural course of the rivulet is into the Earnsdale Lodge, at the other end of which the stream continues its course between the township of Darwin and Lower Darwin, emptying itself in the river Darwin near Dobholes Bridge. A portion of the stream is intercepted for the town supply, and is conducted to a capacious well-head, and thence into the Service Lodge, from whence the water is distributed to the town. In its course the water conduit receives additional supplies from springs and land drainage. On examination it was found that at several places material contamination was possible. At Tockholes it was liable to defilement by refuse from a farm-yard and by surface drainage. Up to very recently the sewage (including the overflow of cesspools) emptied itself into a small stream a few yards above the intake. There were several other sources of contamination, and in one place there were upwards of two feet of stinking mud removed from one of the streams. There was an arrangement by which the town could be supplied with water direct from the compensation tank or reservoir, but when this water was used it was receiving the whole of the Tockholes contamination. On other occasions all suspended foulness that, under ordinary circumstances, went to form the stinking mud of the service tank, was delivered direct to consumers. The local board are constructing a new reservoir that will not be liable to pollution of any kind. The sewerage of the town is very defective both in construction and in extent. The street sewers are in places very offensive. There is no provision whatever for the proper ventilation of the sewer system; sewer gas is allowed to escape into the interior of houses: and "sewer stink houses" are a matter of common observation. A large part of the town, street after street, has no sewerage or drainage whatever. The so-called River Darwin is for many purposes the chief sewer of the town. In the case of unusual floods this filthy stream overflows into the gardens and ground-floors of the houses on its banks. Its overflow is helped by a considerable and increasing silting up of its channel, arising from the mischievous practice of throwing large quantities of ashes and refuse into its bed. By far the worst feature in the sanitary defects of Darwin is found in the house arrangements for dealing with excrement, ashes, and refuse. With the exception of a few water-closets the cesspools are ill constructed. "The unhealthy condition of some of the tenements," says Dr. Stephens, "well nigh baffles description. In one, consisting of two rooms with windows immovable, there were three closely-huddled, miserably small bedsteads in one room, in which a mother and her seven children slept. This wretched cellar is dark and offensive even in the daytime, and what it must have been at midnight with these eight hapless tenants sleeping there it is difficult to realise. Surrounding the building was a quagmire ankle deep in slush of the filthiest kind, receiving into it all kinds of refuse for 14 tenements. In one case the foundations for a house were used as a receptacle for all kinds of filth from a number of houses, and the medical officer complained of the excreta from a fever case being emptied into the hole. These eminently ill-constructed means of receiving excrement, ashes, and refuse were made more injurious to the public health by the gross neglect of scavenging that had been allowed." He adds that there is more house accommodation than there was ten years ago, but in some of the poorer quarters of the town over-crowding is at present very excessive, and the houses have no means whatever of through ventilation. Dr. Stephens gives statistics of the death rate, and asserts that the high death rate has been contributed to by diseases known to be produced or fostered by neglect of ordinary sanitary precautions. There had been about 1,500 persons affected with fever, and it was found that the drain from a house where a young lady had died from fever in September communicated with the town's water and polluted it. Though a committee of the local board reported in 1861 upon the contamination of the water supply by sewage, there is no difference between the present state of the water supply and that which the board condemned 13 years ago. Miles of streets remain unpaved and unsewered. The number of deaths from the fever epidemic is over 100. The town needs a careful survey of the waterworks, completion of the sewer system, proper ventilation of sewers, &c.; a hospital for epidemic diseases, a public mortuary, and means for disinfecting clothing and bedding.

Metropolitan Water Supply.—The official report of the Local Government Board on the water supply of the metropolis during the month of December, states that the condition of the water at the Hampton, Molesey, and Sunbury intakes was generally bad. At the Chelsea Company's intake at Ditton it was good on only three days of the month, and very bad on twenty days. It is added that Parliamentary powers are to be applied for to obtain a new intake at Molesey. Major Bolton describes the progress that is being made by various companies, especially the East London, Kent, and New River Companies, in introducing constant service supplies. Attention is called to a clause in the Board of Trade regulations prohibiting waste pipes being carried down into drains, instead of having the end exposed to the air.

Liverpool Medical Institution.—The following have been elected office bearers for 1875:—President: Mr. McCheane, Vice-Presidents: Mr. T. Shadford Walker, Dr. Davidson, Dr. Steele, Dr. Desmond. Treasurer: Dr. Oxley. Honorary Secretary: Dr. Lyster. Hon. Sec. Ordinary Meeting: Dr. Glynn. Hon. Librarian: Dr. Wm. Carter. Committee: Dr. John Bligh, Mr. Edgar A. Browne, Dr. W. Macfie Campbell, Dr. Caton, Dr. Dickinson, Dr. Grimsdale, Mr. Harrison, Mr. Newton, Mr. Rushton Parker, Mr. Puzey, Dr. Turnbull, Dr. Waters.

NOTICES TO CORRESPONDENTS.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

NOTICE TO SUBSCRIBERS.—Subscriptions in advance for 1875, at the reduced tariff of 2ls. per annum, post free, are now due, and will be thankfully received by the Publishers in London, Dublin, and Edinburgh.

ERRATUM.—The name of the Auditor of the Junior Surgical Society of Ireland, from whose pen we recently published an interesting communication on the "Progress of Surgical Science," was erroneously stated as J. Fitzsimons. Our contributor's name is "Cuthbert C. Fitzsimons."

DR. LANE, Douglas.—If possible, in our next.

DR. A. T. H. K.—The work is announced, but we believe it has not yet been published.

DR. ADAMSON.—Your note has been forwarded to the writer of the article to which you refer, who will probably answer your inquiry by private note.

DR. PHILLIPS is thanked.

AN AGED BROTHER.—Our obituary of to-day records the death of a member of our profession, at the ripe old age of 96, in the person of Mr. James Dawson. It is so rare an occurrence that any of our members approach so nearly to centenarianism that we take the opportunity of drawing attention to the fact. True, Dr. Parr is said to have lived nearly a century and a half, but then the profession of the present day do not generally indulge in Parr's Life Pills!

COMMUNICATIONS, Enclosures, &c., have been received from—Dr. Baltazar Foster, Birmingham. Dr. Adamson, Bellaghy. Mr. Coulter, Chatham. Dr. Abrath, Sunderland. Mr. Morson, London. Mr. Benson, London. Mr. Needham, London. Dr. Williams, Colchester. Dr. Birch, London. Dr. Hime, Sheffield. Mr. Lawford, London. Dr. Pinder, Harpinhey. Mr. Butcher, London. Dr. Kiernan, Buckfastleigh. The Registrar-General, Mr. Ravenstein, London. Mr. Austin, Liverpool Medical Institution. Mr. Aston, Kirton-in-Lindsey. Dr. Donkin, London. Dr. Clarke, Dunmurray. Dr. J. Stannus Hughes, Dublin. Dr. Walker, Bonmahon. Dr. Murdoch, Magherafelt. Dr. Fryer, Fenagh. Dr. Nason, Kingstown. Dr. Nixon, Shirrone. Dr. Thomson, Belturbet. Dr. Ringland, Lisbane. Dr. Walsh, Castlebar. Dr. Sterling, Thomastown. Dr. Perceval, Dublin. Dr. Brady, Rathgar. The Registrar-Mercer's Hospital, Dr. Diamond, Rasharkin. Dr. Roundtree, Ballinacollig. Dr. Huston, Ballow. Mr. Dickinson, London. Dr. McCabe, Dundrum. Dr. Cardiff, Ballinabola. Dr. Rawson, Ballyglass. The Marquis of Drogheda. Dr. Phayer, Kilkenny. Dr. Mahon, Westport. Dr. Dillon, Ennis. Dr. Meadows, London. Mr. Berry, Wigan. Dr. Lane, Douglas.

MEETINGS OF THE LONDON SOCIETIES.

THURSDAY, Jan. 21st.—Royal Institution, 3 p.m. Prof. P. M. Duncan, "On the Grandeur Phenomena of Physical Geography." Hunterian Society, 8 p.m. Mr. H. W. Kiallmark, "On a Case of Cancer of the Liver."

FRIDAY, Jan. 22nd.—Quekett Microscopical Club, 8 p.m. Mr. T. Charters White, "On the Aquarium as a Field for Microscopical Research."

Clinical Society, 8 1/2 p.m. Mr. T. Holmes: "Notes of a Case of Subperiosteal Excision of Os Calcis." Dr. Thorowgood and Mr. Bywater Vernon will bring forward a "Case of Optic Neuritis, with Complete Loss of Vision; Recovery under Treatment." Mr. F. Thornton, "On a Case of exceeding Frequency of the Pulse."

MONDAY, Jan. 25th.—Medical Society, 8 p.m. Ordinary.
TUESDAY, Jan. 26th.—Royal Institution, 3 p.m. Mr. E. Ray Lankester, "On the Pedigree of the Animal Kingdom."

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.
Cutaneous Medicine and Diseases of the Skin. By Hy. S. Pardon, M.D. London: Baillière, Tindall, and Cox.
Manual of Pathological Anatomy. By Drs. Handfield Jones and E. H. Sieveking. London: J. and A. Churchill.
Lectures on Pathological Anatomy. By Drs. Wilks and Moxon. London: J. and A. Churchill.
On Winter Cough, Third Edition. By Horace Dobell, M.D. London: J. and A. Churchill.
Half-Yearly Retrospect of Medicine. By Drs. W. and J. Braithwaite. London: Simpkin, Marshall, and Co.
On the Curative Effects of Baths and Waters. Translated from the German by Dr. Weber. London: Smith, Elder, and Co.
British Wild Flowers in Relation to Insects. By Sir John Lubbock, F.R.S. London: Macmillan and Co.
Three Months after Date. By M. Laing Meason. London: Ward, Lock, and Tyler.
Disclosures in connection with the Medical and Surgical Practice of the Sunderland Infirmary. By G. A. Abrath, M.D.
Nature. Le Mouvement Medical. Le Progrès Medical. The Westminster Review. Public Health. La Tribune Médicale. Journal de Théraputique. Archives of Electrology and Neurology.

VACANCIES.

University College Hospital. Resident Medical Officer. Full information from Mr. Robson, Secretary to the Council.
St. George's and St. James's Dispensary. Accoucheur. Honorary. Election 11th prox. Full particulars of the Secretary.
Hull General Infirmary. Dispenser. Salary, £100 to a fully qualified man. Applications to the Chairman of Committee.
Ulverstone Union. Medical Officer. Salary, £20, exclusive of fees. Applicants must address the Clerk to the Guardians, Ulverstone.
Birmingham Free Hospital for Sick Children. Two Acting Physicians. Emolument, £50 per annum; attendance three days per week. Applications to be sent in to the Medical Committee not later than the 3rd prox.
Stafford General Infirmary. Assistant House Surgeon. Salary, £25, with board, &c. Address the House Surgeon.
Kilchrean Parochial Board, Argyshire. Medical Officer. Salary, £60. Address, Mr. W. J. Martin, Ri-cruin, Lochgilphead.
Birmingham General Dispensary. Resident Surgeon. Salary commencing at £130 per annum. Applications to the Secretary.
Bath Royal United Hospital. Resident Medical Officer. Salary, £100 per annum, with board and residence. Application to the Secretary.

APPOINTMENTS.

BARLOW, J., M.R.C.S.E., Assistant Medical Officer to the Towns Hospital, Glasgow.
BATE, G., M.R.C.S.E., Assistant Medical Officer to the new Woolwich Union Infirmary at Plumstead.
BROOKHOUSE, J. O., M.D., Physician to the General Hospital, Nottingham.
BROWN, W. J., M.B., Assistant Medical Officer at the Borough Lunatic Asylum, Newcastle-on-Tyne.
BROWNE, J. W., M.D., Sanitary Officer for the Belfast Urban Sanitary District.
CROKER, G., M.D., Sanitary Officer for the Belfast Urban Sanitary District.
DAVIS, H. A., M.D., Superintendent Medical Officer of Health and a Sanitary Officer for the New-port (co. Mayo) Rural Sanitary District.
FALVEY, F. J., L.R.C.P.Ed., Superintendent Medical Officer of Health for the Tralee Rural Sanitary District.
HOLLIS, E., M.B., Resident Surgeon to Chalmer's Hospital, Edinburgh.
HUMPHREYS, H., M.A., M.R.C.S.E., Medical Registrar at the Middlesex Hospital.
IRWIN, W., L.R.C.P.Ed., L.R.C.S.I., Medical Officer for the Manorcunningham Dispensary District of the Letterkenny Union, co. Donegal.
LEWELLYNS, R. R., M.R.C.S., House Surgeon at the London Hospital.
LOWE, J., M.D., Medical Officer of Health for the Downham Rural Sanitary District.
LYELL, R. W., M.D., M.R.C.S., Surgical Registrar at the Middlesex Hospital.
LYNCH, F. J., M.D., Superintendent Medical Officer of Health for the Loughrea Rural Sanitary District.
M'CONNELL, A., L.R.C.P.Ed., Sanitary Officer for the Belfast Urban Sanitary District.
M'CREA, J., M.D., Sanitary Officer for the Belfast Urban Sanitary District.
MACKENZIE, M. B., M.D., Sanitary Officer for the Belfast Urban Sanitary District.
MACKENZIE, S., M.B., Medical Registrar at the London Hospital.
MARK, J., M.D., Sanitary Officer for the Belfast Urban Sanitary District.
MARTIN, J., L.K.Q.C.P.I., Sanitary Officer for the Belfast Urban Sanitary District.
MEADOWS, H., M.B., Public Analyst for the Borough of Leicester.
MILLS, J., M.R.C.S.E., Administrator of Chloroform to St. Bartholomew's Hospital.
NEWETT, E. H., L.R.C.P.Ed., Sanitary Officer for the Belfast Urban Sanitary District.
PAGE, H. W., M.B., F.R.C.S.E., Surgical Registrar at the London Hospital.
RIMMINGTON, F. M., F.C.S., Public Analyst for Dewsbury.
RYAN, J., M.D., Superintendent Medical Officer of Health and a Sanitary Officer for the Killdysert Rural Sanitary District.
SAUL, W. W., M.D., Surgeon to the Gaol at Lancaster Castle.
SMITH, R. D., M.R.C.S.E., Junior Resident Medical Officer at the London Hospital.
SPEDDING, B. H., L.R.C.P.Ed., Sanitary Officer for the Belfast Urban Sanitary District.
WRIGHT, E. A., M.B., C.M., Junior House Surgeon to the Huddersfield Infirmary.

Deaths.

ADAMS.—On the 18th Jan., at his residence, 22 St. Stephen's Green, Dublin, Robert Adams, M.D.
 DAWSON.—On the 17th Jan., at Wray Castle, near Ambleside, James Dawson, F.R.C.S., aged 96.
 DESPLAN.—On the 1st Jan., at Knowle, Bristol, Henry Desplan, M.R.C.S.E., aged 41.
 DICK.—On the 20th Sept. last, John Dick, M.D., of Naseby, New Zealand, late of Douglas Bridge, Strabane, co. Tyrone, aged 58.
 EVANS.—On the 11th Jan., at his residence, 5 Stephen's Green, Dublin, D. Thomas Evans, M.R.C.S.E., in the 64th year of his age.
 FITZPATRICK.—On the 11th Jan., at Torquay, Dr. John Fitzpatrick, M.D., of Bolton Lodge, Naas, aged 83.
 HARRIS.—On the 7th Jan., Henry Harris, M.R.C.S.E., of Beigate, aged 60.
 JONES.—On the 30th Dec., John E. Jones, M.R.C.S.E., of Stonehouse, Gloucestershire, aged 54.
 JONES.—On the 12th Jan., at Beaumaris, Sontha Elizabeth, the beloved wife of Llewellyn Jones, M.D., aged 72.
 KING.—On the 11th Jan., at Portland Place, Camberwell, S.E., Thos. Kirwan King, M.D., in his 72nd year.
 LEONARD.—On the 7th Jan., at Princes-Baborough, J. Leonard, M.R.C.S.E., aged 74.
 LIVINGSTONE.—On the 1st Jan., at St. John's, New Brunswick, William Livingstone, M.D., of Kilsyth, Stirlingshire, Scotland, aged 71.
 LLOYD.—On the 2nd Jan., Dr. Wm. Lloyd, of Braithwaite Road, Birmingham, aged 76.
 STEPHENS.—On the 7th Jan., at White House, Emworth, Hants, Daniel Wells Stephens, M.D., aged 48.
 VINTER.—On the 4th Jan., John H. Vinter, M.R.C.S.E., of Guy's Hospital, aged 22.

Advertisements.

SURGICAL SOCIETY OF IRELAND.—The FOURTH MEETING of the SOCIETY will take place on FRIDAY EVENING, 22nd JANUARY, 1875.

Chair will be taken at half-past Eight o'clock precisely.
 B. WILKS RICHARDSON, F.R.C.S.I., } Hon. Secs.
 HUMPHREY MINCHIN, F.R.C.S.I., }
 Royal College of Surgeons, Dublin,
 25th day of Nov., 1874.

ARMY MEDICAL DEPARTMENT.
 11TH JANUARY, 1875.

AN EXAMINATION OF CANDIDATES FOR COMMISSIONS in the Medical Department of Her Majesty's Army will be held in London on the 15th FEBRUARY, 1875, and following days.
 Candidates having the necessary qualifications to practise Medicine and Surgery under the Medical Act, and who are unmarried, and not under 21, nor above 28 years of age, are eligible to attend.
 Application for the printed Schedule, prior to the Examination, should be made in writing, without delay, to the Director-General, Army Medical Department, War Office, London.
 As the list will be closed on Saturday, the 6th February, all schedules and necessary certificates must be returned on or before that date.
 (Signed) W. M. MUIR, Director-General.

INDIAN MEDICAL SERVICES.

NOTICE is HEREBY GIVEN, that an EXAMINATION OF CANDIDATES for Twenty Appointments as Surgeon in Her Majesty's Indian Medical Service will be held on the 15th February, 1875, and following days.
 Copies of the Regulations for the Examination, together with information regarding Pay and Retiring Allowances of India Medical Officers, may be obtained on application at the Military Department, India Office, London, S.W.
 The necessary certificates must be submitted to the Military Secretary at least a fortnight before the date fixed for examination.
 (Signed) T. T. FEARS, Major-General,
 Military Secretary.
 India Office, 7th January, 1875.

The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the insertion of announcements, from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

The scale of charges is as follows:—

Seven lines and under	£0 4 0
Per line afterwards	0 0 6
One quarter page	1 5 0
Half-page	2 10 0
One do.	5 0 0

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

ROYAL FREE HOSPITAL, GRAY'S INN ROAD.—There is a vacancy for a JUNIOR HOUSE-SURGEON to this Hospital. Candidates, who must be possessed of a Medical or Surgical qualification from one of the Examining Boards of the United Kingdom, are requested to send in their Testimonials to the Secretary on or before WEDNESDAY, the 20th inst. The appointment will be made for six months only, but the holder will be eligible for re-election. Board and residence are provided in the Hospital.

JAMES S. BLYTH, Secretary.

ST. BARTHOLOMEW'S HOSPITAL and COLLEGE.

CLASSES FOR THE UNIVERSITY OF LONDON. MATRICULATION EXAMINATION.

TWO CLASSES are held at ST. BARTHOLOMEW'S HOSPITAL in each year, for the convenience of Gentlemen who are preparing for the Matriculation Examination at the University of London—from October to January, and from March to June.

- (1) Classics, French, English, Modern } Malcolm Laing, M.A. Trin. Coll.,
 Geography, & English History. } Cambridge.
- 2) Mathematics and Natural Philo- } The Rev. J. T. Bell, M.A., late Fel-
 sophy. } low of St. Catherine's Coll.,
 Cambridge.
- (3) Chemistry T. Elhoff, F.C.S.

The Class is not confined to Students of the Hospital.
 Mr. Laing also holds a Class for the Preliminary Examination in Arts of the Royal College of Surgeons and of Apothecaries' Hall.

PRELIMINARY SCIENTIFIC EXAMINATION.

A Class in the subjects required for the Preliminary Scientific Examination is held from January to July, and includes all the subjects required, as follows:—

- Chemistry H. E. Armstrong, Ph.D.
- Botany The Rev. G. Henslow, M.A.
 Cantab., Lecturer on Botany
 to the Hospital.
- Zoology and Comparative Anatomy... Norman Moore, M.B. Cantab.,
 Lecturer on Comparative Ana-
 tomy to the Hospital.
- Mechanical and Natural Philosophy P. J. Hensley, M.D. Cantab., Fel-
 low of Christ's College, Cam-
 bridge, Demonstrator of Me-
 chanical and Natural Philo-
 sophy to the Hospital.

FIRST AND SECOND M.B. EXAMINATIONS.

Special Classes in the subjects required for this Examination are held by the Lecturers on those subjects and the Medical Tutor.
 For further information, application may be made to the Warden of the College, St. Bartholomew's Hospital.

M.D. EXAMINATION.

A Class in Logic is held for this Examination by William Graham, M.A., late Scholar of Trinity College, Dublin.

ST. BARTHOLOMEW'S HOSPITAL and COLLEGE.

SCHOLARSHIPS IN SCIENCE.

TWO SCHOLARSHIPS IN SCIENCE have been Founded at St. Bartholomew's Hospital:
 1. An OPEN SCHOLARSHIP of the value of £100, tenable for one year, to be competed for in September. The Subjects of Examination are Physics, Chemistry, Botany, and Zoology. The successful Candidate will be required to enter at St. Bartholomew's Hospital in October next.
 2. PRELIMINARY SCIENTIFIC SCHOLARSHIP of the value of £50, tenable for one year, to be competed for in October next, by Students of the Hospital of less than six months' standing. The subjects of Examination are identical with those of the Open Scholarship. For further particulars and syllabus of subjects application may be made, personally or by letter, to the Warden of the College, St. Bartholomew's Hospital, London.

DUBLIN INFIRMARY for DISEASES of the EYE and EAR, Ely Place.

Ophthalmic and Aural Surgeon:
 ARCHIBALD HAMILTON JACOB, M.D. Dub., F.R.C.S., Ex-Ophthalmic and Aural Surgeon to the City of Dublin Hospital.

Consulting Physician:
 EVORY KENNEDY, M.D. (Hon. Caus.) T.C.D. and Edin., Fellow and Ex-President King and Queen's College of Physicians.

Consulting Surgeon:
 GEORGE H. PORTER, F.R.C.S.I.; M.Ch. T.C.D. (Hon. Caus.) Surgeon in Ordinary to Her Majesty the Queen in Ireland; Fellow and Ex-President, R.C.S.I.; Senior Surgeon to the Meath Hospital.

Obstetric Physician:
 JOHN CRONYN, M.D., F.R.C.S., Examiner in Midwifery, Roy. Col. Surgeons; Ex-Assistant Physician Rotunda Hospital.

Work, Income, and Expenditure for Twelve Months, ending June 30, 1873.

Annual number of Dispensary patients	5,847
Number of visits paid by such patients	124
Number of patients within the Infirmary	163
Number of operations performed	£37 15 0
Total gross expenditure per bed per annum	1 10 6
Average expenditure per interna patient	

The Infirmary is wholly dependent on private benefactions, and is in debt to the Medical Officer. SUBSCRIPTIONS ARE EARNESTLY SOLICITED

The Medical Press & Circular.

THE COMPARATIVE MORTALITY OF LARGE TOWNS. (a)

By BALTHAZAR FOSTER, F.R.C.P.L., M.D., L.K.Q.C.P.I., Professor of the Principles and Practice of Medicine in Queen's College, Birmingham; Physician to the General Hospital, &c.

As the time at my disposal is short, I have drawn up in a tabular form the statistics on which my remarks are based. The table gives the rate of mortality from all causes, and certain special causes, for twenty years (1851 to 1870), in Birmingham and six other large towns, as compared with the rate of mortality in the country generally (England and Wales) and in twelve healthy rural districts. The registration districts, I should observe, do not correspond with the boroughs in the cases of the six provincial towns. In each instance, the registration district is limited to the worst part of the town, and so the comparison is a fair one, except in the case of Bristol. The registration district of Bristol includes not more than one-third of the city, and that the most unhealthy part; the death-rate, consequently, appears much higher than that of the whole city. In the case of London, on the other hand, the area of the registration district is so wide that the death-rate is lowered by including the suburban districts with the central portions of the city in a common average. A glance at the second column of the table shows that the death-rate of the Birmingham district, from all causes, places our town higher in the health scale than Liverpool, Manchester, Leeds, and Sheffield (I omit

Bristol, for reasons above stated); while our death-rate is greater than that of London, and exceeds that of the whole country by about 4 per 1,000. The towns lower in the health scale exceed that of the whole country as follows for the twenty years:—

Sheffield.....	6·5 per 1,000
Leeds.....	6·5 per 1,000
Manchester.....(nearly)	10 per 1,000
Liverpool.....	13·7 per 1,000

The reduction of this excess is the work before the sanitary authorities in these districts. Passing on now to the next column, which shows the fever death-rate, Birmingham stands exceedingly well, being, with London, for the twenty years' average, the healthiest of the six great towns, and for the last decade having a lower fever death-rate than the average of the whole country. Liverpool, which is by far the worst of the great towns in its fever death-rate, has a population which suffers from true typhus, a form of fever exceedingly rare in Birmingham. After this column, however, the superiority of Birmingham ceases, and we come to the two great blots in its sanitary records. The diarrhoea and cholera death-rate in the next column shows that the Birmingham diarrhoea death-rate is twice as bad as the average of the whole country, much worse than that of London and Bristol, about equal to that of Sheffield and Leeds, and is only exceeded by the death-rate in Manchester and Liverpool. If we take, however, the proportion between deaths from this class of diseases and the deaths from all causes during the twenty years, as stated in column 9, Birmingham stands second in this black list, being only surpassed by Liverpool—the most unhealthy of our great towns. Moreover, when we bear in mind that, during these twenty years, Liverpool has suffered from several cholera epidemics, while Birmingham has enjoyed a wonderful immunity from this terrible pest, we cannot, I am afraid, truly say that Birmingham is much healthier than even Liverpool in respect to the mortality from diarrhoea. It is true the town has improved a little during the last ten years, but not sufficiently to justify any complacent indifference to

(a) Read at the Sanitary Congress held in Birmingham January 14th.

the deplorably high death-rate from this cause. The next column refers to diphtheria. Here again the results are startling. Birmingham is the worst great town in England as regards diphtheria, and this unenviable character has been acquired during the last ten years. The death-rate from this disease having gone up from '07 to '34 per 1,000 in the ten years; or to state it more plainly, nearly five times as many deaths have occurred from diphtheria during the latter decade as in the former. A difference in registration will not account for this, as such a cause would have operated equally in other towns, and, moreover, the throat disorders, which are confounded with diphtheria, are not (with the exception of scarlatinal sore-throat) commonly fatal, and would not therefore affect the death-rate. As regards this disease, Birmingham stands not only as the worst of the great towns without exception, but has a mortality nearly double that of most of them. Taking a momentary glance at two other columns in the table, a total zymotic death-rate and the proportion of deaths from zymotic diseases to death from all causes, we see that Birmingham is a little better this decade than for that ending in 1860. Comparing Birmingham with other towns for the first ten years of my table (the figures for the other towns for 1861 to 1870 not yet having been published by the Registrar-General) Birmingham was the worst town of all, except Liverpool and Sheffield, as regards the proportion of zymotic deaths to deaths from all causes. I specially refer to this, because these diseases are what we call and call properly—"preventible diseases," diseases which depend for their propagation on neglect of sanitary laws—diseases which admit of being partially, some would even say very largely, stamped out. The simple statement that the death-rate in Birmingham from preventible disease has been for twenty years past about 7 per 1,000, or that more than one-fourth of the total deaths has been from this cause, hardly conveys the magnitude of the evil. Every year there are now some 2,000 deaths from this class of preventible disease, and during the twenty years considerably over 30,000 persons have died in Birmingham from a class of disorders largely reducible by strict sanitary measures. During the year which has just closed, the death-rate of the borough has gone up to the very high rate for Birmingham of 29 per 1,000, after having stood for the three years 1871, 1872, and 1873 at an average of 24.3 per 1,000. The increase has been caused by the prevalence of certain zymotic diseases, especially small-pox. From this cause alone during this one year 637 persons have died, a number greater than the total deaths which occurred from small-pox during the ten years 1861 to 1870. The remainder of the table I will not enter on, but would briefly refer to those two great sanitary defects which I have pointed out—viz., the diarrhoea and diphtheria death-rates. Both of these classes of disease are eminently preventible. Diphtheria, when it was first studied in France, was referred to the poisonous effluvia from decomposing sewage. This view has again of late been greatly strengthened, and there is a strong opinion in the medical profession that diphtheria is especially a disease which is very closely connected with defective drainage. It often prevails epidemically in rural districts in localities where such conditions exist, and is rather a disease of the country than of the town. In Birmingham, however, it has apparently taken up permanent quarters, and must, consequently, have found some local conditions specially favourable to its development and propagation. To these I will refer a little later on. In diarrhoea we have a still older enemy, one that has always prevailed in the town. The Medical Officer of the Privy Council, in his report for 1858, specially investigated the causes of the prevalence of diarrhoea in Birmingham and other towns, and he summed up his report with these words: "The excess of mortality has in all the places been coincident with one or other of two definite local circumstances—the tainting of the atmosphere with the products of organic decomposition, especially of human excrement, and the habitual drinking of impure water." Sewage-polluted earth, tainted air, and impure water are the great

factors of diarrhoeal disease, and there is reason to believe that diphtheria depends on somewhat similar unsanitary conditions. The question now naturally arises—are there special conditions in Birmingham favourable to the development of these diseases, and, if so, what are they? We have not far to go for an answer. In this town in 1870, the end of the period covered by my figures, there were 70,000 houses connected with privies and middens in the town. These houses contained a population of 325,000. In the words of the report of the Sewage Committee: "The middens cover an area of 13½ acres, and practically all of them, containing faecal matter and solid and liquid refuse, are open to the air. Some of them are situated beneath houses or workshops, and large numbers are built against the walls of houses, which are thus permeated with the filthy liquid soaking through the walls. The consequence is that the sewers are constantly fouled by the drainage from the middens, and that the surface wells generally become the receptacles of sewage matter, with which the earth surrounding the middens is absolutely saturated."

By our own words are we judged. The water of these surface wells, polluted with sewage, as our medical officer of health has frequently shown, is at present used by at least one-third of our population. Some 140,000 people in this town drink this death-giving fluid, and especially the children under five years of age, on whom the mortality from diarrhoea and diphtheria falls most heavily. The remedies for this state of things are obvious; they are two—(1) the abolition of the midden system, and the substitution of a system of weekly removal of refuse of all kinds from every house. This is the system which has been for years in operation in some of our healthiest towns. I am glad to say the Corporation are vigorously endeavouring to carry it out here. The next remedy (2) is the abolition of all surface wells, and the substitution of a constant supply of the purest water we can get. If, by any means, a stream of pure water is poured into our courts and yards, in place of the tainted well-water which is now used, our health conditions in Birmingham will be greatly improved and our mortality from preventible diseases largely diminished. This work, which you, sir, have proposed during your tenure of office, is our most urgent sanitary reform, and will, when accomplished, give a special honour to your mayoralty.

The following is the Table of Mortality per 1000 inhabitants, from all causes and certain special causes, in Birmingham and eight other Districts, during twenty years; the first line of each bracket referring to the period from 1851 to 1860, and the second from 1861 to 1870:—

Registration District.	Death-rate from all Causes.	Fever ("Typhus" of Registrar-General).	Diarrhoea and Cholera.	Diphtheria.	Scarlatina.	Total Zymotic Death-rate.	Proportion of deaths from each cause to deaths from all causes.	
							Zymotic per cent.	Diarrhoea per cent.

A BRASS RING LODGED IN THE LARYNX FOR FOUR YEARS. (a)

REMOVAL BY SUBHYOIDEAN LARYNGOTOMY—CURE.

By GEORGE M. LEFFERTS, M.D.,

Surgeon to the New York Eye and Ear Infirmary, the Demilt Dispensary (Throat Departments); late Chief of Clinic to Prof. Stoerk, in the Imperial University of Vienna.

CASE.—A. B., aged six and a half years. Four years ago (August, 1870) the child, while playing in the company of other children with an ordinary, medium-sized, brass finger-ring, broken at one point, placed it in her mouth, and a few moments later suddenly swallowed it. Urgent dyspnœa immediately followed; the child became deeply cyanotic, then unconscious, and suffocation seemed imminent, until one of the bystanders, passing her finger deep into the child's throat, felt the ring and pushed it downwards. This act was followed by immediate improvement in the respiration. The child recovered consciousness, and soon afterwards was able to move about at play.

On the physician's arrival, a short time later, various instruments were passed into the throat in order to seize the ring, but without success, and no foreign body being met with during the examination, it was supposed to have passed into the stomach, and further attempts at removal were desisted from.

Cathartics were administered and the evacuations carefully watched, but without finding the missing body.

The child's respiration is stated to have remained good during the remainder of the day of the accident; but the same night the mother noticed that it was decidedly stridulous, and says that it has since remained so. The child, however, slept quietly, and had no attacks of laryngeal spasm. Deglutition was not and has not been affected. The child, immediately after the accident, became partially aphonic, and has continued in the same condition during the subsequent period of time up to within six weeks. A short, hacking cough made its appearance a few hours after the ring was swallowed, and has persisted since that time.

Several physicians were summoned at different times during the few weeks following the accident, and occasional instrumental examinations of the throat were made. (It may be here stated that no laryngoscopic examination had been made previous to the one made by me.) Emetics, laxatives, and cough-mixtures were ordered, and the mother was assured that the presence of the ring within the air-passages was extremely doubtful. The above narration of symptoms comprises the history of the case during the following period of time—nearly four years—up to six weeks ago. Within this time there was no change in the symptoms as described, nor were any new ones noticed, except that the child gradually lost flesh and strength.

Six weeks ago the child contracted a heavy cold. The respiration immediately became seriously embarrassed. The voice was entirely lost, and laryngeal spasm occurred for the first time, principally during the night. The attacks were prolonged and severe; the child becoming relaxed and cyanotic, then gasping for breath, and tearing at the throat with both hands; but the intensity of the spasm passing off in a few seconds, deep inspirations followed, the face assumed its natural hue, and the patient again fell into a natural sleep.

Lately these spasms have increased in frequency, so that she may have from two to six during the course of one night. Any exertion or excitement during the day will increase the number and severity of the attacks at night. A fit of crying alone has often provoked serious

and protracted laryngeal spasm. Although the voice has been entirely lost for the last six weeks, and all of the symptoms have pointed to a very serious interference with the function of the larynx, deglutition has not been at all affected. The child does not, nor has not, complained of any pain during the process, and has always taken, with equal facility, solid or fluid food, a curious fact, to be noted when the location of the ring in its relation to the laryngeal parts comes to be described.

The condition of the child becoming so serious, the mother was advised by her friends to leave her home in the country and come to this city for medical advice.

She here consulted Dr. J. Lewis Smith, who upon making an auscultatory examination detected the presence of the missing foreign body within the respiratory tract.

The doctor referred the case, as one of unusual interest, to Dr. J. R. Leaming, who, after making his examination, directed the case to me, for the purpose of having a laryngoscopic examination made.

My report having been made, the child subsequently was most courteously referred to me for treatment by Dr. Smith.

Operation.

In the present case it was deemed advisable to modify the original operations by first performing tracheotomy, and thereby insure the patient a free and plentiful supply of air during the steps of the operation—a procedure rendered doubly advisable by the condition of laryngeal stenosis existing in the case, and the liability to laryngeal spasm (as shown in the previous history), as well as the danger of subsequent inflammatory action reducing still further the calibre of a larynx already diminished more than one-half from its normal condition.

It was proposed to make the presence of the tracheal tube but temporary, and it having subserved its first purpose of protecting the patient from danger during the operation, to remove it as soon as danger from the laryngeal inflammatory process had passed away.

The operation was accordingly undertaken July 7th, 1874, as follows: The head having been thrown backwards over pillows placed beneath the neck, and the position of the cricoid cartilage having been identified, an incision some two and a half inches in length was made over it, in the median line, and extending downwards over the superior portion of the trachea. The skin and superficial fascia being rapidly dissected through, the inner borders of the sterno-thyroid muscles came into view, and after drawing them aside by means of retractors, a few touches of the knife laid bare the cricoid cartilage, and with it the isthmus of the thyroid body lying immediately below, across the trachea,—in this case being unusually large and lying high up. During this dissection several medium-sized vessels were severed, and a halt was here made until they had been secured by torsion. The isthmus was then displaced, partly by pushing it downwards and partly by tearing through its substance, a procedure which I have several times adopted and have never experienced any trouble nor unusual hæmorrhage from its laceration, contrary to what I believe to be the generally held opinion. The isthmus being partly removed in this manner, the upper rings of the trachea became plainly visible, and all active hæmorrhage having ceased, a hook was placed under the lower edge of the cricoid cartilage to steady the parts.

An incision was then made in the trachea, from below upwards, commencing at about the fourth ring, and continued up to the cricoid cartilage. The tracheal dilator (Trousseau) having been introduced and the lips of the incision held apart, the canula was readily introduced and secured in position.

Spasmodic cough followed, expelling a moderate amount of clear mucus untinged with blood, but ceased after the further administration of ether through the tracheal tube.

The second step of the operation consisted in, first, identification of the position and relations of the hyoid bone, a procedure not unattended by some difficulty on

(a) We are indebted for this and for Dr. Wagner's paper in our last issue to early sheets kindly sent by the authors. Some delay has occurred with the latter paper, for which we would apologise to Dr. Wagner, and it has therefore appeared in full in America before a portion was printed in our pages.—Ed. M. P. & C.

account of the small size of the parts and the close proximity of the hyoid bone to the thyroid cartilage, a limitation of the field of action which renders the performance of this operation upon a child much more difficult than upon the adult.

This point having been satisfactorily ascertained, an incision three inches in length was made parallel with the lower border of the hyoid bone and one-eighth of an inch below it, transversely across the neck, and the skin, subcutaneous cellular tissue, the superficial fascia with the internal fibres of the platysma myoides, the inner half of the sterno-hyoid and thyro-hyoid muscles being carefully divided on each side of the median line upon a director, introduced successively between the various layers, the thyro-hyoid membrane was reached and laid bare without difficulty and with very little hæmorrhage, no arterial branches having been encountered. Two veins which lay across the track of the wound, immediately below the platysma, were of such a size as to render ligature advisable, and having been raised by dissection from their beds, were secured by double ligature and then severed.

The thyro-hyoid membrane being now divided by an incision of less extent than the one through the superficial parts, thus giving a funnel-shape to the wound, the cushion of cellular and adipose tissue lying between the base of the epiglottis and the parts external to it, together with the laryngeal mucous membrane to either side of it, were disclosed, the latter being prolapsed outwards as soon as the tense pressure of the thyro-hyoid membrane was removed, and could be seen to be drawn inwards with each inspiration.

The most important and difficult step of the operation now follows—important as regards the danger of wounding the epiglottis, and certainly rendered more difficult by the vagueness of the description given of its mode of performance by Malgaigne and others, and the omission of the consideration of important anatomical points which must influence it.

Malgaigne says, (a) and his description of the operation has always been considered the classical one, and is the one which has been followed by those who have performed the operation: "After incision of the thyro-hyoid membrane and those fibres of it which go to the epiglottis, the mucous membrane is reached; seize this and divide it also; the epiglottis then presents itself."

Prat, (b) in describing the steps of his operation, says that he proceeded to divide the tissues, layer by layer, until he reached the thyro-hyoid membrane; after cutting this through, the epiglottis presented itself.

Follin (c) states that he divided the cushion of adipose and cellular tissue which lay in front of the epiglottis (after cutting through the thyro-hyoid membrane), and, lastly, incised the laryngeal mucous membrane and opened the cavity of the larynx.

This stage of the operation would, according to these accounts, seem to be indeed a comparatively simple one; but I have not found it to be as described. My dissections and experimental operations upon the cadaver have shown me that after the thyro-hyoid membrane has been divided transversely, a thick layer of cellular and adipose tissue, extending usually from the hyoid bone above to the thyroid cartilage below, forming the cushion of the epiglottis, and lying between it and the parts external, presents itself; to either side of this mass mucous membrane protrudes. This membrane consists of the broad anterior portions of the ary-epiglottic folds at about the point where they join with the sides of the epiglottis—is therefore laryngeal mucous membrane, and an incision made through it transversely and directly inwards, or even with the point of the knife directed upwards and backwards, would open directly into the laryngeal cavity, not

alone by cutting through the anterior extremities of both these folds, but in so doing necessarily dividing also by the transverse incision the cellular and adipose mass lying in front of the epiglottis and between them—would cut through this cartilage at about its middle, or a short distance below that point.

Follin's description of the steps of his operation illustrates this point fully, and demonstrates the danger of such an incision; for by making it he cut across the epiglottis and penetrated directly into the laryngeal cavity.

It is needless to say that this accident is to be carefully avoided. Such an opening into the cavity of the larynx would render, according to several authors, a clear view of its interior impossible, and would certainly defeat, to a great extent, the purposes and advantages of the operation.

How, then, are we to avoid section of the base of the epiglottis? By, after having reached this point in the operation, inserting a tenaculum into the cellular and adipose mass described above, and by means of it drawing the epiglottis forcibly downwards. This puts its ligamentous attachments to the hyoid bone and tongue upon the stretch, draws it away from the former, and leaves an appreciable interval of space between them through which the knife—its point directed upwards and backwards, and kept near the hyoid bone—can be readily passed, and will be found to have penetrated the mucous membrane between the base of the tongue and the epiglottis, the aim of the incision.

The epiglottis being drawn downwards in this manner, mucous membrane will still present itself laterally; but a moment's reflection will show that this is no longer laryngeal. The displacement of the epiglottis has carried downwards with it both ary-epiglottic folds, and the mucous membrane which we now have presenting is a portion of that situated between the base of the tongue and the epiglottis. The incision needs now only to be carried through it on either side, including the few ligamentous fibres which run from the epiglottis to the hyoid bone, and which are seen in the median line; to lay open the pharynx, and to have the epiglottis present itself uninjured to view. A digital exploration by the mouth, made previous to incision of these parts, affords an important aid in diagnosing their relations. The size, form, and ligamentous attachments of the epiglottis, especially in its relation to the hyoid bone, vary greatly in different cases. If the index-finger of one hand, however, be introduced into the mouth, not only the tip, but also the base of the epiglottis can in the majority of cases be reached and felt; should two fingers of the other hand now be placed upon the hyoid bone, a diagnosis as to their approximative relation can be readily made, and will usually be found to be so satisfactory in its results, and will afford so much certainty to the operator during his future proceedings, that it should in no case be omitted.

In carrying out the further steps of my operation especial care was therefore given to this point, which I have endeavoured to make clear in as few words as possible, and the importance of which I think merits careful attention on the part of the operator.

The parts immediately below the thyro-hyoid membrane having been exposed as described above, a tenaculum was inserted near the hyoid bone, into this thick cushion of cellular and adipose tissue, and strong traction downwards made to accomplish the purposes already mentioned. To insure still further certainty, a small incision was made into the left lateral projecting fold of mucous membrane, and a director was passed inwards, and then directly across, coming out at a corresponding point upon the opposite side of the wound, and through the projecting mucous membrane at that point. It should therefore lie in the groove or furrow between the base of the tongue and the epiglottis, and a digital exploration by the mouth confirmed the point.

Nothing now remained in order to complete the operation but to incise the tissues lying over the director. This was done, the direction of the knife being upwards and backwards, and the pharynx was opened.

(c) *Archives Générales de Médecine*. Février, 1867.

The epiglottis immediately came into view, not, however, being pushed into the wound, as stated by Malgaigne, and was seized and drawn outwards through the incision. A perfect and most satisfactory view was now afforded of the superior laryngeal parts, and the ring was seen lying in the position as previously demonstrated by the laryngoscope.

In order to remove it with as little laceration of tissue as possible, my intention was to have cut through it at two points by means of a cutting forceps, and, having removed the upper fragment, to displace and bring away the remaining and smaller ones by drawing them out through the tissues in which they lay imbedded.

On attempting this, however, and making the firm pressure on the forceps necessary to cut through so thick a substance, the ring was felt to give and rotate slightly. This fact being ascertained, a moment's manipulation with a small forceps resulted in disentangling it from its attachments, and in bringing it safely out through the external wound.

In closing the wound I modified somewhat the methods of former operators, and I think with good result. The general practice has been simply to introduce three or four deep sutures, and then to keep the parts in apposition and at rest by flexing the head upon the chest. The method which was carried out in my case was: First, to unite carefully the divided edges of the *mucous membrane* by means of fine thread sutures, the knots being tied so as to lie inwards.

No difficulty was experienced in its accomplishment, and the good result was made manifest by the fact that at no time subsequently, during the process of healing, was there escape of air through the external wound, nor discharge of fluids during deglutition, even though the latter process was at times, by order, forcibly conducted.

This having been done, deep wire sutures, three in number, were then introduced to bring together all of the deeper tissues, the ends being brought out through the external wound, and finally the latter closed by means of the interrupted suture.

The subsequent history of the case was most satisfactory and rapid in its progress towards a cure.

HOME-WORK FOR THE MEDICAL MISSIONARY.

By EDWARD LANE, M.A., M.D. Edin.

THE proper distribution of work in the world—the scientific allocation of parts among the *dramatis personæ* who are carrying on the great business of life before our eyes, so that each collective body in the community, and every individual composing it, may be enabled to fulfil to the uttermost the functions for which they are respectively best qualified—is surely a consideration of the very highest interest and moment. With all that there is to be done in the world, with the appalling social difficulties that everywhere look us in the face, and which, in spite of the very best organisation will, no doubt, continue for generations to baffle the greatest efforts, it is evident that in order to be able to make any headway whatever amid the “sea of troubles” that surrounds them, mankind cannot afford to lose one particle of the effective power at their command; and the advance of practical enlightenment in our own day demands a very serious inquiry as to whether or not that is indeed the condition of things under which we are actually living. Looking to the world as it is, and having regard more particularly to the condition of its majority, the working classes, the question arises—Is the distribution of parts assumed by those who benevolently labour in their behalf entirely the best in the circumstances? is as much done for the poor and ignorant as might be done by another and superior organisation? or, on the contrary, is it not a fact that those who have hitherto chiefly worked, though in a missionary spirit and with the highest of motives, among the poor,

are not by special education the best qualified for the task, while another educated section of the community most distinctly are? It will be seen, of course, that I refer to the comparative suitability for the great work in question, in its present phase, of the clergyman and the doctor as chief actors, and I shall ask the reader to follow me for a few minutes while I endeavour to explain why I consider the latter to be a much more potent agent for the time being than the former.

At the foundation of the subject is the tremendous problem, the condition of the working classes in our day, more particularly in the great towns; and here, of course, I do not so much refer to the class of mechanics and skilled labourers generally. Their general condition, though bringing them, as well as their employers of the wealthy classes, partially within the scope of my observations, as will presently appear, is yet so much better by comparison than that of the lowest stratum of society—the really poor—that for the moment we may pass them by, and speak only of the *residuum* of Mr. Bright—the lowest round of all on the social ladder.

After all that is written day by day in the press, and published to the world in various forms in the reports of philanthropists, it would seem scarcely possible to add materially to the knowledge of the better classes as to the condition of their most indigent and degraded brethren. And yet probably the truest adage that reflection on life ever produced is the familiar one which asserts that “the one half of the world does not know how the other half exists.” We hear in London of St. Giles’s and Shoreditch and Whitechapel; but what do we know of their denizens, except a kind of wild *fama*, which reports of the very depths of physical, mental, and moral degradation? They might, for any knowledge of, or community of feeling with them, be the inhabitants of another town, another country, almost of another planet. And yet the tremendous fact remains, and must be solemnly attended to if we would avoid the violent disruption of society from its base, that side by side with, in the very midst of, so much wealth, so much refinement, and all the evidences of an advanced civilisation, exists in the modern world, and especially in our own England, a condition of our poorer brethren who compose the large mass of society, which equals almost anything in savagery anywhere, and would often contrast unfavourably with the state of the Red Indian in his wig-wam, or the Hottentot in his mud cabin. Into all the causes of so terrible a phenomenon it would be impossible to enter here without far surpassing the limits and the object proper of these remarks. If it were suggested, moreover, that the fundamental and greatest reason of all, as also that which it is most difficult to cope with, is the one here, as in all old countries, of surplus numbers—the excess of population, in accordance with the great discovery of Malthus—a very vexed question in economics would be opened up, carrying us away from the more practical object I have in view. The time cannot be far off when the scientific discussion of this crucial problem must engage the serious attention of the Legislature, as it has already that of the profoundest thinkers in political economy, and when it must be settled as a question of pure science, capable of demonstration, and apart from the likings or dislikings of friends or foes. But whatever be the organic solution, we cannot wait for it. On the facts themselves, at any rate, all are agreed. Everyone knows that a fiery volcano of vice and want, ignorance and supreme degradation, lies immediately under our feet. Hitherto, indeed, in spite of many rumblings, the subterranean fires of wretchedness and discontent have been kept under in England—thanks partly to the inherent qualities of the national character, with its orderliness, its power of endurance, and its reverence for superiors—partly to a highly organised state of society, where wealth and education in the hands of the few have sufficed hitherto to guide and restrain the many. But what we have so lately witnessed in France, ill-luck might at any time

bring to our own doors. England, too, might awake one day, stifled with the moral nightmare of a *Commune*. Those, I say, are the facts, patent to all, and they constitute a state of things so serious in their height and depth and surpassing difficulty, that they might with truth be termed the one great problem of modern life, beside which all others are so minor in importance as scarcely to be worth taking into account.

In considering the deplorable condition of the poorest among the labouring poor, and the means of their elevation, one point strikes us at the outset as cardinal and of chief moment, and it is this—they need help in every way, that is certain. All that benevolent effort of every kind and from all sides, ever so well directed, can effect among them will not be too much; but if one thing is more certain than all the rest it is this—that until their physical condition is bettered, it is vain to look for any marked improvement among them. In attempting to work in their behalf, it is necessary to begin at the very beginning, and the first great lesson to be inculcated—however laborious it may be—is how to live, *physically*. That, indeed, is the very first grade, and by far the most important one, in the general educational movement which is just commencing. *How to live*, consistently with the now well-established laws of health, in such wise that bodily health, in so far as it depends on themselves, may first be the result; and along with it, the cleanliness, decency, and self-respect, the comparative morality, the absolute increase in humanity, which due attention to it will not fail to engender speedily. That is the work to be commenced among our poorer brethren, and it may well be termed Herculean, for literally the Augean stables of physical filth, entailing moral degradation, have first to be swept out. And to whom is society entitled to look as the chief labourer in this vast field of usefulness as the one most competent by education and training to carry the work out? Unquestionably it is to the doctor. The Legislature has of late given practical recognition of the truth of this in the vast extension of medical officers under the Public Health Act; but, however excellent that measure may be, it goes but a very short way, and it is not too much to say that nothing that can be done by Parliament will really touch more than the merest outside and fringe of the evil. If you cannot make men moral and sober by Act of Parliament, neither can you hope to make them cleanly nor obedient to the laws of health generally, even if they knew them. For this purpose teaching, persuasion, and encouragement are indispensable. It is the *inside* of the abode that most wants visiting, and it is there that the doctor's systematic labour must begin, if there is to be a chance for any large amelioration in the condition of the lowest poor. That is perhaps a new idea, the result of a very altered estimate of the full and proper functions of the medical man in the time to come. In the history of the past one figure has been more conspicuous than all the rest as a labourer among the poor in the spirit of charity, and to his eternal honour, it is that of the clergyman. His object, of course, has been twofold, that of ministering, according to his light and ability, to physical want, and that of winning souls—the latter, no doubt, the stronger motive of the two. And who shall estimate the amount of good thus done? Who can calculate the humanising influence, the benign effect, of the mere presence among the dregs of humanity, of men bringing with them minds enlightened by a liberal secular education and hearts chastened by the sublime lessons of religion? But yet, impelled as he is by the purest and highest of motives, the clergyman is really not the most efficient possible labourer in that field at present; and having an eye to the work to be accomplished, I believe the doctor would be. For what is the immediate and pressing work to be done, which, left undone, neutralises all other efforts at amelioration in the condition of the lowest of our poorer classes? Properly considered, it is in the main a *material* work in the first instance. It is neither more nor less than an endeavour to rescue a large, and the largest, part of our population from the extreme

of physical degradation. If we inquire into the two main causes of this condition, we shall find that they consist—first, as already hinted, of the bane of over-population; secondly, of that of ignorance—the latter partly a cause and partly a consequence of the former. To speak of that ignorance as of the profoundest character is, of course, only to state a truism; but I confine myself here to the blank ignorance of the fundamental laws of health—of those laws in the recognition and observance of which lies, as it seems to me, the sole hope of any really great improvement in the condition of the people generally, and most especially of the lower orders.

To an onlooker, and one indoctrinated in the organic physical laws that govern the human economy, which are the result and outcome of centuries of the closest physiological investigation all over the world, it does seem a startling and most singular reflection, that in an age especially scientific, the knowledge of the laws of health, in ever so elementary a form, should not anywhere—certainly not in Great Britain—find a place in the curriculum of an ordinary education. So far as the writer is aware, it may be stated as an incontrovertible fact that nowhere in these islands, from the Universities of Oxford and Cambridge down to the poorest village grammar school, is physiology systematically taught as a necessary branch of general education—physiology, which instructs us in the nature of the functions of the different organs of our bodies, informs us of their requirements in order that we may have health, and is indeed the absolute code and standard of physical well-being. Such a fact is surely one of the most remarkable anomalies ever witnessed, and would seem to constitute one of the strangest shortcomings in logic in the whole history of mankind. It might well have been, and indeed would have been highly characteristic, in the pre-scientific era of the world, when men's minds were dominated so largely with the monkish idea of mortifying the flesh in lieu of conserving it; of despising and vilifying the greatest and most beautiful of God's material works—the human frame—instead of endeavouring, in love and reverence, to comprehend its marvellous structure and the infinite wisdom displayed in the adaptation of means to ends in every part of it. But the fruits of that ignorance are abundantly evident in all directions over the face of society. They are awful among the poor; mitigated, but still disastrous, among the rich. I will not pause to give more than a glance at the kind of effects produced on the latter; but they are seen from infancy to old age. In the first place, if an elementary knowledge of anatomy and physiology is at present a blank in the education of the *men* of the upper classes, in that of the women it not only is non-existent, but the demand for it, or the possession of it, would seem to be accounted barely modest and respectable. It is not, according to the refined notions of society, a proper thing that a lady should be tainted with such vulgar knowledge as that she is an item in the animal creation at all—an ornament to it, certainly, but still one of its component parts; a being with organs that have to be maintained in health by scientific care, as in the case of all other animals; and all the more, since it falls to her lot to bring others into the world, and to be for years almost their sole guardian, their earthly providence. How can this be properly done if the mother is herself ignorant of the very rudiments of the subject, and has been taught, besides, to regard it as a kind of knowledge not properly belonging to her, but an affair of the doctors, or nurses, or some one else than herself? We are not wholly to blame her. She has not been taught, and she only errs along with those who should be wiser. Then the boy, the young gentleman, goes to school, and the proverbial *three R's* once made sure of, he is duly, often painfully, indoctrinated in the usual cycle of knowledge—history, geography, mathematics, languages, living and dead—all no doubt with their great uses, and he may end by “unsperring the soul of Plato;” but never a word does he hear of the most important of all facts to him, that he is a being whose bodily constitution is under fixed laws, inexorable as fate, on the observance of which

depends health, and with it happiness and success in life—without it, misery and failure more or less complete. With such a preparatory education, the man is ushered in the world to play his part. Have we a right to expect that he will play it with wisdom, that he will husband and preserve his powers so as to employ them to the very best advantage to himself, his family, and the world? Assuredly not, and the mournful fact is, that even under the comparatively favourable conditions of the upper classes, from want of this most important knowledge of one's own physical self, not one life in twenty yields the fruit that might fairly have been expected of it.

(To be continued.)

Transactions of Societies.

THE MEDICAL SOCIETY OF LONDON.

MONDAY, JANUARY 11TH.

MR. VICTOR DE MERIC, F.R.C.S., President, in the Chair.

MR. HENRY SMITH related the particulars of
A CASE OF MALIGNANT TUMOUR OF THE LEG REQUIRING
AMPUTATION.

He was requested to see a gentleman, *æt.* 51, who was intensely gouty. Six months before he had noticed a small swelling at the middle third of the front of the leg, which, though painless, slowly increased. A country practitioner saw it and treated it, puncturing it twice, when nothing but a little blood was evacuated. When seen by Mr. Smith it was a soft, somewhat flattened swelling, about the size of a medlar, situated over the front of the tibia, just at the junction of the upper with the middle third, adherent to the skin and gradually slid off to the bone. He at once pronounced it to be a malignant tumour, and recommended that an attempt should be made to remove it, and if necessary, that amputation should be performed. Another surgeon who was consulted advised the same course, but recommended amputation through the knee-joint, to give the patient a better chance of non-recurrence of the disease. The patient was most anxious to save his knee, and as there was plenty of room to amputate below it, Mr. Smith rather inclined to his view; but as the other and senior consultant expressed a strong opinion against it, he amputated through the knee, sawing off the condyles, and the patient has done well since. On examination, the tumour was found to be of a medullary kind, involving the bone extensively on its surface, and extending deeply down, only, however, for a very limited space, into the medullary membrane. There were several inches of healthy bone between this point and the knee. Mr. Smith was anxious to obtain the opinion of the Fellows upon the question as to whether the better plan would not have been to amputate in such a case through the continuity of a healthy bone, or to cut beyond it through the joint. Eminent surgeons were divided in opinion on this point, and his own old teacher, Sir Wm. Fergusson, was assured from his own large experience that it was neither justifiable nor necessary to amputate beyond this bone when there was plenty of healthy tissue to cut through. Sir James Paget and others, on the contrary, held the opinion that there was much more chance of a recurrence of the disease if the bone involved were not entirely removed. This, Mr. Smith thought, was a very serious point to settle, as we know for a certainty that amputation of the thigh in a man beyond the prime of life is fatal in 25 or 30 per cent. of the cases, whereas in amputation below the knee the mortality is reduced to at least one-half of this; but with regard to the liability of recurrence of the disease being greater or less after each operation, there was, as far as he knew, no reliable information.

The PRESIDENT said, if he were to be operated on himself, he would choose the greater operation, though the rate of mortality was higher in it, to the more serious danger of the disease not being eradicated by an insufficient operation.

MR. MAUNDER remarked that his principle of acting in these operations was, that the tumour being local, and the

constitution not infected, to cut widely round the tumour, so as to ensure its total removal. In a similar case to that of Mr. Smith he cut through the knee-joint with the happiest results, the long anterior flap being used (there being retraction in the posterior) to the extent of five inches; the patient has an excellent stump, and there had been no return of the disease for three years. He advocated the removal of a whole organ if part were affected. In cases of scirrhus we removed the whole breast: why should we not the whole bone when this was attacked?

MR. BRYANT regretted that Mr. Smith had not given the vertical section of the bone, as then we could have ascertained the exact extent of the cancerous disease. He could not entirely endorse Mr. Mauser's principle as regards the removal of the whole of one organ when attacked with malignant disease; for when the lower third of the tibia was diseased, surely it was not necessary to amputate at the knee-joint, but in the upper portion of the bone. He highly approved of Mr. Smith's operation at the knee in this case, but criticised his division of the condyles, as this at once produced section of the bone exposed the patient to the danger of pyæmia.

MR. GANT agreed with Mr. Smith, and cited several cases of similar operation which did well.

MR. ROYES BELL discussed the subject fully, and gave an instance of a child similarly operated on which recovered in a week.

MR. SMITH replied briefly.

MR. BRYANT read a paper on

THE LEAST SACRIFICE OF PARTS,

which, he maintained, ought to be a leading principle of surgical practice. He explained more fully the principle as one that forbids the surgeon to sacrifice more of the body than the absolute necessities of the case demands; that calls upon him to remove the disease that requires removal, but no more; that enables him in accidental surgery to make a flap for an amputation wherever he can, and in some cases to make no flap at all, but to leave the case to Nature to repair; and in pathological surgery to cut through tissues infiltrated with inflammatory deposits rather than go above a joint or take away more of a limb than the necessities of the case demand. He condensed the subject into three main propositions, each of which he illustrated by cases. The first proposition was, "That in cases of disease or accident no more of the body is to be taken away than the necessities of the case demand," and he illustrated this chiefly from the surgery of the foot. He said that at first sight the proposition might appear to be a truism; but he went on to ask any hospital surgeon if it be not true that in cases of disease of the metatarsal bones or joints we are not too apt to regard any individual case as a good one for Chopart's operation, a Piragoff's or a Syme's, according to our own fancy or appreciation of the value of one or other of these operations; and if we are not too prone to forget that a good recovery of the foot may ensue on the removal of the diseased bone or bones without any amputation at all. In support of this view he then quoted from the able advocate of Syme's amputation, as given in "Holmes' System," 2nd edition, vol. v., who expresses his mature opinion, after much experience, "that Syme's amputation is calculated to supersede entirely that of Chopart, besides taking the place of amputation of the leg in the majority of cases formerly supposed to demand it." The author then stated that he entirely dissented from these views of the learned writer. He believed that from local disease alone no form of amputation of the foot should be entertained until less severe measures have been employed and failed; that when amputation of the foot is called for, the minimum amount of foot should be taken away; that when a Chopart's operation will suffice, a Piragoff's should not be thought of; that when a Piragoff's is applicable, a Syme's should not be entertained; and that an amputation of the whole foot is never to be undertaken when the disease can be removed by less severe measures: for he cordially agreed with Hancock, when he asked the question in his college lectures—if anything can be more unphilosophical than to advocate the sacrifice of any bone or joint of the foot for no other reason than that a particular operation should be performed? He stated that the remarks already quoted are as applicable to other parts as they were to the foot, and asked if it were not true that fingers and thumbs were often removed in cases of injury that, if left to Nature, might often be saved, in order that the surgeon may make a clean amputation. Do we not see joints excised that might be saved by free-incisions, or the removal

of necrosed bone? and amputations performed above a joint, or high up a limb, in order that good flaps may be made? He then passed on to illustrate all these points by cases, quoting at first seven cases of disease of the different tarsal bones cured by the removal of the diseased bone, and three of extreme disease treated respectively by Chopart's and Syme's amputation, or amputation of the leg. He then made some remarks upon the wisdom of the surgeon in cases of disease of the bones of the foot being satisfied by the removal of the dead bone, never having met with a case in which the resection of a tarsal bone was called for, for bone he said, that was not dead was reparable, and that to take this away is too often to take away that which, if left alone, would make good the parts that have died. The author then proceeded to illustrate the value of the proposition by treatment of cases of diseased joint, and dwelt for some time upon the value of free incision into suppurating joints. He read the headings of thirteen cases successfully treated by this method, and stated his belief that a free cut into a disorganised articulation is rarely followed by any other than a good result; that when the suppurative process is due to synovial disease, a recovery without further surgical interference may be looked for; when due to local necrosis, the incision helps Nature towards the recovery of the cure by expediting the process of exfoliation, and the subsequent removal of the bone by either natural processes or some surgical proceeding; in more severe cases the incisions giving relief and in no way adding to the mischief. The treatment of disease of the joints due to local necrosis was then considered, and a very interesting series of cases read, ten cases being given, including examples of disease of the shoulder, elbow, hip, knee, and ankle-joints, in which recovery followed the removal of dead bone from the articulations. The author stated that in no class of cases is the principle of "the least sacrifice of parts" better shown, and expressed his belief that in one or all of the cases quoted, if this practice had not been adopted, excision or amputation would have been resorted to. The 2nd proposition was then considered: "That to carry out this principle the surgeon may in pathological amputations fearlessly divide tissues infiltrated with organised inflammatory products, and even cut through the walls of suppurating cavities, or through diseased joints, more particularly to save amputating above a joint." He illustrated this proposition by the particulars of ten cases, in all of which recovery took place. The 3rd proposition was lastly considered: "That in accident surgery, parts irreparably injured are alone to be removed, and no healthy tissues are to be sacrificed in order to perform a recognised and probably a named operation; that to these ends the surgeon ought to utilise even doubtfully useful integument, or even leave a stump to granulate when by so doing some portion of the shaft of a bone can be left, a joint saved, or amputation above a joint avoided. In the surgery of the hand this practice was strongly advised, more particularly in thumb injuries. Amputation of a thumb, useless, smashed irreparably, the author condemned, and under all circumstances the irreparably injured parts ought alone to be taken away, and doubtfully viable skin left. Cases were then quoted to illustrate the proposition: ten of the toes; one of the foot—a Chopart's amputation, in which a long anterior flap was made—one of crushed arms, which was left to Nature to granulate, and a good stump left; two of crushed legs, in which a rapid recovery followed amputation at the knee-joint; and one of ruptured popliteal artery, treated in the same way with success. The author then concluded by stating that he could still further illustrate the value of the principle "that of the least sacrifice of parts" from bone surgery, pointing out how Sir W. Fergusson had always urged the removal of tumours of the jaws from within, and Sir J. Paget, the tumours of bone generally by enucleation. He wound up by expressing a strong opinion in favour of the principle, and said he had for many years acted upon it, and had deviated from it only on very strong evidence of the necessity for so doing.

The PRESIDENT complimented the author on the lucid style of his propositions, but reminded him that attempts to save parts often failed. He would like to know what dressings were used.

Mr. ADAMS remarked that the author's cases involved the great principles of conservative surgery. He briefly reviewed the fall of amputation and the rise of conservative surgery under the hands of Brodie, Syme, Fergusson, and others. Excision was first advocated, but now it appeared that Mr. Bryant advocated simple incision into the joint, and he believed Mr. Gay was the first to carry out this practice.

Mr. HENRY SMITH said that Mr. Bryant's views were by no means new; he had learnt the practice of incising joints that were suppurating many years ago from Mr. Gay; it was a mode of proceeding which he highly approved.

Mr. BRYANT, in reply, said he did not in the cases he had mentioned lay any claim to novelty, but advocated the great principle of conservative surgery. The dressing he used was dry lint enveloped in cotton-wool, not with a view of excluding germs, but of keeping up an equable temperature.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JANUARY 12TH, 1875.

Dr. C. J. B. WILLIAMS, President, in the Chair.

ON THE PATHOLOGY OF LUPUS ERYTHEMATOSUS.

By Dr. GEORGE THIN.

The author gave a description of the clinical features of the disease, and of the opinions held by various authors—viz., Cazeuaye, Hebra, and others, on the pathology of the disease. As regards its pathological anatomy, the author stated that microscopical examination of the skin in various stages of the disease by Neumann, Giddings, and Kaposi, has shown that there is great vascular congestion around the sebaceous and sweat glands, more or less destruction of the glands themselves, and cell-infiltration of the surrounding corium. Dr. Thin had had an opportunity of examining the skin of a man who died under Hebra's care in Vienna in 1873, in whom the disease had begun to show itself in the part examined—viz., on the dorsum of the foot and toes, only a few weeks before death. He removed a portion of the skin from the inner surface of the second toe, beyond the area of the sebaceous glands. He found the sweat glands, the rete Malpighii, and the fibrillar tissue perfectly normal in appearance. There was, however, enormous dilatation of the capillaries, which was most marked in the papillae and around the sweat glands, the contour of the pilated vessels being mostly indicated by the red blood-corpuscles with which they were filled, but the vessels themselves being visible in some of the sections. The small veins were also distended by blood-corpuscles. The fact that this condition of the capillaries was found in such an early stage of the disease, and before any other changes, and that it would, if persistent for any length of time, give rise to all the changes in the tissues described by other observers, led the author to doubt whether lupus erythematosus primarily affects the glands of the skin. The author stated his belief that, in the present defective state of our knowledge of the pathological anatomy of the disease, dilatation and distension of the capillaries is the earliest morbid condition which has been detected, and that this would correspond with stasis of the circulation during life. A well-executed drawing of the microscopical appearances was shown.

Mr. JONATHAN HUTCHINSON inquired why erythematosus lupus should be considered specifically distinct from other forms. Speaking only from an examination with the naked eye, he did not know any features which would suffice to distinguish it. Whilst in some forms the sebaceous glands appeared to be especially affected, as in the form first recognised by Mr. Startin, who called it "sebaceous lupus," in others the sweat-glands are more so, whilst the rarest form is that which comes on acutely, especially affecting the vessels, and accompanied by hæmorrhage. Probably, on the examination of a large number of cases, all the structures of the skin might be found affected, in some the sebaceous, in others the erythematosus element preponderating, and in the latter cases the cicatrix left might alone decide that it was really lupus. The diagnosis between the common and the erythematosus form was very difficult, resting chiefly on the absence or small quantity of deposit in the latter. Both occur chiefly in young people. Mr. Hutchinson had seen a case at the age of eighteen months, and Kaposi one at three years; in both there was a scrofulous tendency, and in both there was a slow spread and little general disturbance. The chief difference was in the treatment, cauterisation, as Hebra has stated, being less successful in these cases, probably because there is less cell-growth.

Dr. DRYSDALE regarded the disease as a variety of scrofula from the fact of its leaving a scar, the age at which it occurred, and the family history of the patients. Cod-liver oil!

in large doses, and painting the part with equal parts of biniodide of mercury and lead ointment was therefore the most successful treatment.

Dr. THIN, in reply, said that there was not practically the difficulty in distinguishing the disease from lupus vulgaris which Mr. Hutchinson believed, as was shown by the experience in the St. Louis Hospital, where they are well recognised. The absence of destructive change extending into the subcutaneous tissue is a strong point of difference from lupus vulgaris. The absence of ulceration, and the common history of an origin in early life, were also distinctive. He objected to the term "scrofulide," as the disease occurred in robust healthy men in the prime of life.

ON AN EPIDEMIC OF MALARIOUS YELLOW FEVER ON BOARD H.M.S. "DORIS," OFF PORT ROYAL, JAMAICA, IN 1873.

By Dr. HAYNE.

The author called attention to the distinctions between "malarious" and "specific" yellow fever, the one being remittent, the other continuous; in the latter albuminuria occurs, but not in the former. The facts of the outbreak are briefly these:—The *Doris* was at Port Royal from May 14th to May 21st, thence it went to Kingston till the 27th, and started for Nassau on the 28th. Both Port Royal and Kingston were at the time stated to be healthy, with no yellow fever; the temperature was from 84° to 85°, the weather calm, and the malarious odour from the shore, from which the ship was about 150 yards distant, was very unpleasant at night. The first case occurred on the day of leaving Kingston, the patient being seized with giddiness, nausea, and headache; the temperature was at first normal, but subsequently 103°, remaining high till the sixteenth day. There was no albuminuria, and the patient was convalescent on the twentieth day. The course of the temperature closely resembled that of typhoid fever in its later periods. Two fresh cases occurred on the following day, one of which resembled the first, but the other was a severe case. The man had been exposed whilst intoxicated on shore to malaria, and he died on the fourth day with black vomit, melæna, and convulsions. Eight fresh cases occurred between May 29th and June 9th, four of which were mild, three more severe, but the vomiting was only bilious. The ship was ordered to proceed northwards, and although eleven more cases occurred, they were all mild; out of the whole twenty-two cases only one being fatal, and that alone being accompanied by the black vomit. In most cases the onset was sudden, with feverishness, præcordial oppression, giddiness, and nausea; the temperature in mild cases raised only 1° or 2°, in severe 6° or 7°, the hot stage lasting three or four days. There was no albuminuria.

A discussion then took place on the question of the real nature of the disease in these cases, and on the distinctions between the so-called "malarious" and "specific" yellow fever, in which the following Fellows took part: Dr. Gilbert Smith, Inspector-General Lawson, Dr. Fayer, Dr. Wickham Legg, Dr. Duka, and Dr. Leared.

MEDICAL MICROSCOPICAL SOCIETY.

ANNUAL GENERAL MEETING, JANUARY 15TH.

The President, Mr. JABEZ HOGG, in the Chair.

THE election of officers for the ensuing year having been taken,

THE PRESIDENT proceeded to deliver the annual address. After a few words of congratulation on the present status of the Society, its sound financial condition, and the good work accomplished with a thoroughness and an exactness that must become a precedent for future years, he briefly alluded to a loss the Society, although so young, had already sustained in the death of Mr. Edward Snell, late of Stepney. He went on to say that Mr. Needham had repeatedly urged in committee the expediency of issuing "Transactions," and he was glad to find the question settled in the affirmative by the unanimous voice of the Society. Henceforth proceedings will be published, for the proposal although understood as a tentative measure, there could be no reasonable doubt of its success, and their transactions would become a "Year-Book of Practical Histology." The President urged the exchange of specimens upon the members as a means of comparing and noting work and correcting morbid appearances. Crude

material, he also thought, would be some advantage to exchange, and if embedded in paraffin mixture, could be transmitted in a perfectly solid and safe state through the post; and since it is in contemplation to appoint a Morbid Growths Committee, to whom material forwarded to the Society will be submitted, good results and valuable reports might be looked for in future. The importance of "casual communications" was insisted upon as a means of eliciting useful discussion on practical matters, as in the medical societies, and also the exhibition of specimens under the microscope, with short descriptive notes on the mode of preparation, &c. The value of re-investigating very many points in histological anatomy, and an endeavour to settle vexed questions as to the size, form, and structure of the red blood-corpuscles in man, and their relation to those of the lower animals, a thing of value in medical jurisprudence. The mysterious surroundings of zymotic diseases and the life-history of those incomprehensible organisms said to produce typhoid, variola, &c., require investigation. There is much to be learnt respecting the bacteria and their share in pyæmia. The Germans are fully alive to the importance of such work, and Professor Heiberg, of Norway, is engaged investigating the nature of the *materies morbi* in pyæmia and specific blood poisoning. He has detected schizomycetes in the solid organs and at the actual seat of disease, the kidneys and their tubules, he found plugged by an amorphous granular material, which, upon examination with a power of 600, proved to be chiefly composed of these bodies. In the arteries, going to secondary deposits, and in the areolar tissue around them in pyæmia similar masses of bacteria have been found. The Norwegian Professor, however, attaches much importance to the form or species of bacteria. The spherical-shaped bodies he looks upon as the specific bodies; but Professor Sanderson attributes no great value to any particular species, because when a section of recent disease is moistened with water or even caustic potash both spherical and rod-shaped bodies are in a short space of time developed. The same bodies, indeed, are found in blood, serum, flesh, water, &c., after it has stood by for twenty-four hours. In unsuspected places, as Thames water contaminated with sewage, and in the air we breathe, bacteria at times abound. They have been taken on moistened glass slides exposed over sewers; and although not largely mixed in atmospheric air, it is a significant fact that living organisms are carried about by every breath of wind, and in a fit state to determine the contamination of fluids capable of supporting their existence. These marvellously minute schizomycetes elude the highest powers of the microscope, all we know about them is, that ammoniacal and albuminoid fluids favour their development; but what determines their selective powers, by what peculiar chemical or vital process in a few hours the whole mass of blood is poisoned by them is a mystery, which, like a shadow, recedes from us just as it seems to be within our grasp. The President finished his address with a review of the work of the Society during the past year, which, in his opinion, sustained the reputation the Society had already earned in the work of practical histology and in the promotion of original research in pathological anatomy.

A vote of thanks was moved by Mr. C. WHITE to the President for his address and past services, and also to the Secretaries for attention to the interests of the Society, which closed the meeting. A number of interesting specimens were exhibited by Mr. Groves, Mr. Needham, Mr. Ward, and other Members.

The following is the list of officers for the ensuing year:—

<i>President.</i>	<i>Committee (continued).</i>
Dr. J. F. Payne.	Dr. M. Bruce, Charing Cross.
<i>Vice-Presidents.</i>	Mr. E. C. Baber, St. George's
Mr. Jabez Hogg.	Mr. F. Durham, Guy's.
Mr. Kesteven.	Mr. H. S. Atkinson, King's.
Mr. H. Power.	Mr. J. Needham, London.
Dr. U. Pritchard.	Mr. Geo. Giles, St. Mary's.
<i>Treasurer.</i>	Dr. S. Coupland, Middlesex.
Mr. T. C. White.	Dr. W. S. Greenfield, St. Thomas's.
<i>Hon. Secretaries.</i>	Mr. E. A. Schäfer, University College.
Mr. C. H. Golding Bird.	Dr. W. H. Allchin, Westminster.
Mr. J. W. Groves.	Dr. Foulerton, General Profession.
<i>Committee.</i>	
Mr. J. A. Omerod, St. Bartholomew's.	

THE SURGICAL SOCIETY OF IRELAND.

THE Society met on the evening of Friday the 8th January, Dr. TUFNELL, the President, in the chair.

Mr. H. G. CROLY exhibited a specimen of

CANCER OF THE BREAST

which he had recently removed from a woman in the City of Dublin Hospital. The patient, who was aged 50, was a very strong, healthy-looking countrywoman. The tumour was movable, and there were apparently no glands in the axilla. Having removed the breast by the usual incision, he prolonged the lower incision upwards into the axilla in order to allow him to explore that cavity. He then found there was a chain of lymphatic glands running from the pectoral muscle to the axillary artery, varying in size from a garden bean to that of a pea, and so high did they run in the axilla that he was able to feel the pulsation of the axillary artery under the finger. Another feature of interest was that, notwithstanding the movable nature of the tumour, when the breast was removed the areolar tissue was found to be infiltrated with distinct masses of cancerous tissue, cutting as hard as cartilage. This was important, as showing that the more fat taken away in a breast amputation the better.

Mr. H. G. CROLY exhibited a

HAIR-PIN ENCRUSTED WITH PHOSPHATES REMOVED FROM THE BLADDER OF A FEMALE.

The following are the particulars of the case: A young lady, aged 22 years, residing in the country, was brought to me (said Mr. Croly) by her aunt for the purpose of getting surgical advice in consequence of the sufferings produced by a hair-pin having been introduced into the bladder. She stated that she inserted the hair-pin two months previously to the date at which I saw her. She presented the appearance of a hysterical girl. She stated that she suffered intense pain after passing water; and on further inquiry I ascertained that the urine contained blood, ropy mucus, and phosphatic deposits. I introduced a silver female catheter into the bladder, and readily struck a foreign body, which felt like a soft calculus. I then used Sir H. Thompson's sound, and was enabled to state that a stone was in the bladder, and if the girl's account were true, that most likely the hair-pin formed the nucleus of the calculus. I then decided on operating on a future day, and made up my mind first to crush the calcareous deposit by lithotripsy, and then to endeavour to extract the hair-pin. Accordingly, assisted by Dr. Kidd and Dr. Thornley Stoker, who administered the ether, the urine having been retained for a few hours, I introduced Weiss's modification of Sir H. Thompson's lithotrite and seized the foreign body, which I crushed gently, and then withdrew the instrument. Just as this step of the operation was completed, the patient became violent, and the ether seemed to lose its effect. We accordingly determined not to attempt any further operative interference on that day. I prescribed a sedative draught and a warm hip bath, and desired the urine to be kept for my inspection. A considerable quantity of phosphates was passed, and three days subsequently we met at the patient's lodgings, and, having placed the young lady under the influence of chloroform, I introduced a nasal polypus forceps for the purpose of removing the hair-pin. The pin was easily grasped in the forceps, and the two points appeared at the orifice of the urethra, and just as one end escaped through that orifice it broke off, but a sufficient portion was expelled to allow me to grasp the second leg and withdraw it. The pin, on removal from the bladder, was found to be coated with phosphates. The bladder was washed out to remove any detritus. A warm hip bath was ordered to be given, and repeated if necessary, also a sedative draught. The patient complained for several days of severe pain in the loins, but made an excellent recovery, and had full power over the bladder. My friend Dr. Jacob, of Maryborough, having seen in the notice-paper that I was about to bring forward this case, wrote to me as follows: "I observe that you are about to read a paper on a case of removal of a hair-pin from the female bladder. It will be interesting to you to know that such a case occurred to me about ten years ago, and on an occasion when it was necessary that I should be ready, if not rough, and when I had not more suitable means available than my little finger, which, well lubricated, I used as a dilator, and having reached the foreign body in the bladder with the index finger of the left hand in the vagina,

I adapted the fork of the pin to the bulb of my finger and readily removed it, sent the girl to my infirmary, where she remained for a few days, and left without any vesical difficulty, and with perfect contraction and control of the urethra and neck of the bladder." A few days before the operation (continued Mr. Croly) I procured at Messrs. Fannin's the instrument I now exhibit, which Mr. Breton informed me had been invented for the purpose of removing hair-pins from the bladder, and which they had had for many years in their possession, but had never been asked for it. It seems to me to be very well adapted for the intended purpose, for no matter how the hair-pin is seized, this instrument brings it into the long axis, and withdraws it. I found, however, that the polypus forceps acted well, and therefore did not make a trial of the instrument, but thought it worth showing to the Society. There are a great many methods recommended for removing foreign bodies from the female bladder—either by forcible or gradual dilatation, or removing it by lithotomy. In this instance I adopted lithotripsy, to reduce the size of the body by crushing the phosphatic deposits, so that I could remove the hair-pin without dilating the urethra. It is desirable to avoid dilating the urethra in females, in order not to give cause for incontinence of urine. If dilatation be adopted, it should be rapid, and under chloroform, as slow dilatation is so apt to be followed by incontinence. Though this was the first case of the kind I have met with in my own practice, it would seem that cases of hair-pins introduced into the female bladder are not uncommon. In addition to the case communicated to me by Dr. Jacob, Dr. Edward Stoker showed me a hair-pin which formed the nucleus of a stone which he removed from the bladder of a female. I looked into the works of Bryant and Erichsen, to see if they contained anything in reference to the subject, and I find that Mr. Bryant states that in the Museum of Guy's Hospital there are specimens of a bone bodkin, a cedar pencil, and a stiletto which had been removed from the female bladder. I did not see anything in Mr. Erichsen bearing on the subject. Mr. Croly concluded by saying that he would give the hair-pin to the Curator of the College Museum, to be placed in the case which contained a number of vesical calculi removed from the bladder by him by lithotomy and lithotripsy.

The PRESIDENT said there was one objection in his opinion to the instrument exhibited by Mr. Croly. If the hair-pin was lying across the bladder, and caught in that position, so far from its being withdrawn, it escaped the instrument. It appeared to him that the polypus forceps was the most simple instrument for the withdrawal of such a foreign body.

Dr. ATTHILL said he had had an opportunity of seeing the patient on whom Mr. Croly had operated, and the successful issue of the case had impressed him highly with the skillful manner in which the operation had been performed. In addition to the difficulty of the operation, from the nature of the foreign body, the patient was an hysterical, nervous girl, difficult to treat. Mr. Croly, he considered, adopted a judicious method; the mass in the bladder was of large size, and it was therefore judicious to crush it in the first instance. In the majority of cases it was not difficult to remove foreign bodies from the bladder, because of the dilatability of the urethra, and he did not know of any instance in which incontinence of urine followed. In any of the cases he had had an opportunity of seeing the bladder and the urethra retained their tone. As to the instrument exhibited by Mr. Croly, it struck him there was a serious objection to it. As you draw it down it makes a sweep or segment of a circle, and if the bladder were contracted, as it often was in these cases, the instrument, as it swept round, would be likely to lacerate the mucous membrane of the bladder. The mode in which Dr. Jacob effected the removal of the foreign body by the skill of his hand was therefore preferable.

Dr. QUINLAN wished to call attention to the method first used by Sir Philip Crampton, of making a slight incision on the upper side of the meatus before removing the object. In two cases where he removed foreign bodies from the female bladder, with the advice and assistance of the late Mr. O'Ferrall, he used Sir Philip Crampton's instrument, which was lent to him for the purpose by Mr. Hamilton. It consisted of a conical handle, having a concealed bistoury. This was introduced into the urethra, and he made an incision a line in depth on the upper side of the urethra; then the urethra was easily dilated; and although the dilatation was very great—the stone in one case being larger than a walnut—the urethra contracted very readily, and the bladder regained its power of retaining urine with great rapidity.

Mr. BARTON said that some time ago he removed a hair-pin from the female bladder. The pin was of full length, and coated with phosphatic deposits. It made a very long stone, weighed 36 grains, and was entirely impacted across the bladder. The mode he adopted was that of dilating the urethra by sea-tangle. Two portions were introduced in the evening, and in the morning the urethra was so far dilated that it admitted a third portion, and the next day it was so fully dilated that the forefinger could be introduced into the bladder. The patient was put under chloroform, and he was then able to bring the pin into the long axis and remove it through the urethra. The patient did well. He was aware of what the foreign body was, for the patient admitted that she had introduced the hair-pin on the 3rd January, 1869, and it was extracted on the 1st December of the same year.

Dr. RICHARDSON: Mr. Croly said he was not aware that there was any instrument of the kind he exhibited described; but in the last edition of Sir Henry Thompson's work on "Stricture of the Urethra" an instrument of this kind was delineated, and I think it an improvement on this one. It is tubular, and the hair-pin, when caught, is drawn into it by the force of the screw.

Mr. FLEMING said it would be in the recollection of many members of the Society that many cases similar to the present occurred in this city, and had been published. Sir Philip Crampton removed a hair-pin under similar circumstances from the female bladder, and, like this, it was largely encrusted with deposits. He recollected himself assisting Dr. Hardy in removing a needle-case from the bladder of a woman. In many instances foreign bodies were removed from the bladder without any operation at all, and some of these were detailed in Coulson's work on diseases of the urinary organs. In cases under his own care he had dilated the urethra by the ordinary means, by sea-tangle, and also by sponge tents, and passed his finger into the bladder without any difficulty; and he never had a case in which incontinence of urine was the result. He remembered removing with the greatest ease a mulberry-stone as large as a hazel-nut, by dilating the urethra, and the result was perfectly successful, no incontinence of urine following. They were not, therefore, to apprehend incontinence as a result of urethral dilatation.

Mr. CROLY, in reply, said the chief point discussed was the question of dilating the urethra or not; and whilst he must agree with Mr. Fleming and Dr. Atthill that there was not great risk of incontinence from dilatation of the urethra, yet he thought they must all admit that if the foreign body could be removed without dilatation it would be so much the better. In Dr. Jacob's case, where he removed the foreign body with his finger, it had only been in the bladder a couple of days. Dr. Quinlan mentioned that Sir Philip Crampton had introduced an operation for cutting and dilating. All surgical authorities alluded to cutting and dilating, and some surgeons thought that "vaginal lithotomy" was the only justifiable operation. He exhibited the instrument he had obtained at Messrs. Fannin's as a surgical curiosity. As it had lain in Fannin's for many years, and as Sir Henry Thompson's work was of very recent date, if there was any copying in the matter, it was not on the part of the inventor of this instrument. The polypus forceps had, however, acted very well, and he should be quite satisfied to use it in any future case.

opinion that it is desirable to have a balance in hand to meet the current expenses of the year 1875, decided to distribute an even amount of £3,000, thus leaving a sum of £181 towards the collections of next year. There were forty-one churches that refused, through various reasons, to join in the movement, and thirty-nine returned no answer to the communications sent to them.

The instructions to the Distribution Committee were— firstly, that the system of distribution be based on the amount of the subscriptions received by each hospital, and the work done during the previous year; and secondly, that in estimating the work done they should take into account the following cases only:—Intern patients, extern midwifery cases, and extern accidents; and that the Committee be requested to take evidence as to the approximate relative cost to the hospitals of these cases.

The Committee finally determined to distribute the fund according to the following plan:—

1st. That two-thirds of the £3,000 to be distributed be divided according to the amount of voluntary contributions received by each hospital during the preceding year.

2nd. That the remaining third be divided according to the work done (by each hospital) for the voluntary subscriptions received during the preceding year.

3rd. That 500 extern maternity cases be considered equivalent to one bed maintained throughout the year.

4th. That 1,000 extern accidents be considered equivalent to one bed maintained for one year.

5th. That an allowance of 20 per cent. additional shall be allowed on account of lying-in cases.

The working out of this plan is shown in detail in the accompanying tables, and the Committee has requested the trustees to pay over the amounts therein mentioned to the various institutions participating in the distribution of the fund for 1874.

These amounts are as follows:—Sir Patrick Dun's, £335 17s. 5d.; City of Dublin, £1,160 17s. 2d.; Steevens', £312 0s. 4d.; Cork Street, £121 3s. 3d.; Mercer's, £387 18s. 10d.; Rotunda, £407 1s. 10d.; Coombe, £215 2s. 7d.; St. Mark's (Ophthalmic), £59 18s. 7d. Total, £3,000.

It is to be remembered that the Meath and Adelaide Hospitals refused to participate in the movement, and in consequence, the dividend for each of the participating hospitals was somewhat larger than it would have been if these institutions had joined. The Committee, with the view of showing how the fund would have been divided had these two hospitals been included, estimate the amount that they would have been entitled to, and the consequent result to the other institutions now obtaining share of the fund.

The amounts calculated, from the information furnished by the published reports of these institutions, would appear to be about as follows:—Not participating in 1874—Meath, £435 7s. 11d.; Adelaide, £668 3s. 4d. Participating in 1874—Sir Patrick Dun's, £200; City of Dublin, £739 1s. 6d.; Steevens', £195 4s.; Cork Street, £75 19s.; Mercer's, £245 18s.; Rotunda, £255 11s. 6d.; Coombe, £135 18s. 9d.; St. Mark's, £48 16s. Total, £3,000.

From the foregoing statements it is evident that if th

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 27, 1875.

DUBLIN HOSPITAL SUNDAY.

Dublin Hospital Sunday distribution was de-
last week. The total amount lodged to the credit
fund is £3,317, but from this amount must be
the expenses incurred for the year 1874 up to
which are £124. The Committee being of

collections for 1875 realise the same amount as 1874, and that other institutions participate in 1875, the amount granted from the fund to each institution in 1874 must be looked upon as exceptionally large, and should be considered as such by the managers of the present participating institutions.

Bearing in mind the difficulties under which the Hospital Fund Council laboured, they may be congratulated on the success of the movement, for although they were excluded at one blow from a participation in the charitable collections at all Roman Catholic places of worship, and received with little cordiality, even with hostility, by others from whom encouragement might have been expected, they were able to produce a sum which, if not large, is sufficient to inspire hope of greater success in the future, and to bring waverers into co-operation with the movement.

It is quite obvious, however, on an observation of the sums voted, that the principles set down for the guidance of the Committee are not such as to secure a distribution relatively proportionate to the public value of the institution, or the work done by it. The only test which the public desires to apply to hospitals is the amount of good to the poor which is done with their charitable contribution, and all that they wish to know is that the smallest fraction of their money goes in unfruitful establishment expenses and the largest fraction into the mouths and in alleviation of the pains of the patients.

This consideration seems to have had no weight with the Hospital Fund Council; and when we remember that in some of the Dublin hospitals it costs three guineas for officials to distribute one pound to the sick man, we think that, in the distribution, the most important point has been forgotten.

The view taken by the Council seems to have been that all sorts of extern work should be discouraged, and all intern work rewarded; and that abundance of private resources should be a special claim upon the consideration of the Council. Thus they divided at once two-thirds of the whole sum in proportion to the amount of private subscriptions; and those hospitals like Mercer's, Sir Patrick Dun's, and Steevens', whose income from subscriptions was comparatively small, have been at a monstrous disadvantage in comparison with the City of Dublin, whose resources are wholly derived from private benefactors.

Even in the disposal of the remaining third of the money it seems to us that the almost total exclusion of extern work from the consideration of the Committee was a great mistake, and a great injustice to several hospitals.

We entirely demur to Professor Haughton's view that the statistics of extern departments of hospitals are made to order by the reduplication of worthless cases. *Au contraire*, we are well aware that the intern system is quite as much liable to abuse, especially in hospitals where subscribers' recommendations are influential, and where the beds are accordingly filled with the infirm retainers of my Lady Bountiful; and if the distribution scheme has been constructed for the special advantage of hospitals which are of little use to the sick poor, whose circumstances do not allow of their going into hospital, we think that the Dublin Hospital Fund has been misdirected

from the channel in which the contributors would have desired that it should run.

It seems to us that to calculate 500 extern midwifery cases and 1,000 extern accidents as equivalent to one bed is preposterously inequitable, and we hope that in next year's allocation the representatives of hospitals which have no out-patient department will not be permitted to impose such restrictions. Actual medical relief to the deserving sick poor ought to be the only title of any hospital to a grant, and that relief is quite as valuable when administered to extern cases as to the nominees of hospital subscribers.

SEX IN EDUCATION.

It is to be supposed that many of our readers had the advantage of reading the two interesting essays upon the above important topic which appeared in a spirited London periodical, the *Fortnightly Review*, last year, and which was written, on the one hand, by a very popular male medical author, Dr. Henry Maudsley, and on the other, by the lady who may at present be considered as the champion *par excellence* of female education, Mrs. Garrett-Anderson. The subject-matter for discussion was taken mainly from a work which now lies before us, entitled "Sex in Education, or a Fair Chance for Girls," the author of which is a distinguished physician of Boston, Dr. Edward H. Clarke, late Professor of *Materia Medica* in Harvard College.

Dr. Maudsley, it will be remembered, pointed out that on account of the fact that women were affected during their lives with a function which periodically caused a loss of some portion of the circulatory fluid, there were grave reasons to doubt whether the education of that sex could ever be permitted to be as thorough and continuous as that carried out by men, due consideration being given to the requirements of hygiene. In her retort to Dr. Maudsley, Mrs. Anderson alleged that the experiment of educating women thoroughly had been frequently tried, and the result had been to show that the process was of service, not injurious to the health of female students.

Dr. Clarke, in his little work, has some admirable remarks on the meaning of the word *Education*, which perhaps may go a little way towards reconciling combatants. "Education," he says, "is not used throughout this book in the limited and technical sense of intellectual or mental training alone. By saying that there is a boy's way of study and a girl's way of study it is not asserted that the intellectual process which masters Juvenal, German, or Chemistry, is different for the two sexes. *Education* is here intended to include what its etymology indicates, the drawing out and development of every part of the system; and this necessarily includes the whole manner of life, physical and psychical, during the educational period."

It has been the misfortune, certainly, of most countries in modern times, as compared with Greece in her palmy days, that education has lost this, its primary signification, and has popularly stood for studying without regard to the physical training that used to be considered a *sine qua non* of excellence of character in Athens, and especially in Sparta, both in the case of men and of women. Those who read the *Memorabilia* of Xenophon will remember the

discussion between the great Socrates and a young man who had been neglecting gymnastics and two other exercises enjoined by the sages of Greece. Socrates points out how the mind is apt to languish in a weak, flabby, non-muscular frame, and how much the virtues of courage and endurance of the mind are strengthened by those exercises which develop the frame. "A healthy mind in a healthy body" was the Greek ideal, and surely will again be the ideal of our less spiritual descendants in the centuries which will succeed this great scientific revival.

"The delicate bloom, early but rapidly fading beauty, and singular pallor of American girls and women have almost passed into a proverb. The first observation of a European that lands upon our shores is that our women are a feeble race; and if he is a physiological observer, he is sure to add, 'they will give birth to a feeble race, not of women only, but of men as well.'"

Such are the words of Dr. Clarke, and they will be, we are sure, concurred in by all physicians who have either travelled in the United States or seen many American women in their European haunts. "Circumstances," adds Dr. Clarke, "have repeatedly carried me to Europe, where I am always surprised by the red blood that fills and colours the faces of ladies and peasant girls, reminding one of the canvas of Rubens and Murillo, and am always equally surprised on my return by crowds of pale, bloodless female faces, that suggest consumption, scrofula, anæmia, and neuralgia."

Dr. Clarke is of opinion that the present system of educating girls in the United States is the main cause of this pallor and weakness. He does not assert that it is the sole cause, but only one cause, and one of the most important causes. Other causes of the effect remarked in America are, he says, irrational cookery and indigestible diet, perpetual pies and dough-nuts, and other abominations of the American cuisine.

Much evil he also attributes to the omission of clothing where it is needed, or to excess of it when the body does not need it. The regimen of a college arranged for boys, if imposed on girls, would foster the neglect of the peculiarities of a woman's organisation still more than girls' schools do.

Dr. Clarke says he has seen instances of such educated females in whom the special mechanism of their sex remained germinal—undeveloped. It seemed to have aborted. They graduated from school or college excellent scholars, but with undeveloped ovaries. Later they married, and were sterile. Nature, he says, has reserved the catamenial week for the process of ovulation, and for the development and perfecting of the reproductive system. Previously to the age of eighteen or twenty, he adds, opportunity must be periodically allowed for the accomplishment of this task. Both muscular and brain labour must be remitted enough to yield sufficient force for the work.

We confess we don't see how the work of the world is to go on if maid-servants, as a rule, are to be obliged to give up ordinary work for one week in every four, as it seems Dr. Clarke would like all young women to do. Nor do we think that women of any class in England are, as a rule, much less able for mental or bodily work at the catamenial period, than at others. Of course, we do not speak of delicate women, but of the ordinary women of Britain,

whose constitutions are familiar to all observant practitioners of medicine.

Our own conviction has long been that the climate of the United States is immensely inferior to that of European countries; and this, it seems to us, is the main cause of the comparatively weak state of health of the American young ladies referred to by Dr. Clarke in his interesting volume. There are very few parts of the States where the climate is at all tolerable to a person accustomed to the much abused but excellent climate of these islands. The inhabitant of New York is scorched and baked like a negro in summer; and, on the other hand, freezing to death is not by any means uncommon in winter. Boston is frightfully cold in winter; and, with few exceptions, the whole of the United States seem less favourable to health and vigour than our own continent of Europe. In England there is not a day in the year when a woman need stay indoors. In the States the excessive heat of summer forces them to remain as much indoors in many places as if they lived in India, whilst the terrible severity of the winters of the Northern States make life indoors, with foetid stoves and hot-water pipes, a part of the *régime* of every woman.

Why, then, should we run away with the idea that the women of America are more delicate than the women of England because of their mental culture? *Cæteris paribus*, our well-bred English young ladies are far more thoroughly educated than young American ladies; and yet, the well-mannered and accomplished young Englishwoman has a bright blush of health on her cheeks, and a body whose plumpness gives pleasure to the lover of a happy human existence; whilst the fragile American young lady seems altogether too light and unsubstantial for the critical eye of the physician.

Education of women, in short, like education of men, should be directed towards cultivating the brain and the muscles equally; and if this golden rule of hygiene be observed, we cannot see why women are to be kept in ignorance, or how it will in any way benefit posterity to keep one half of the race in the dark upon all the deepest questions which most interest our happiness. By the study of science alone does mankind advance in knowledge of nature; and we do hope, that women, as well as men, may soon be thoroughly grounded in the main principles of the sciences of the day.

THE SYSTEM OF ELECTION TO EXAMINERSHIPS AND PROFESSORSHIPS IN THE IRISH COLLEGE OF SURGEONS.

MOST of our Irish and those of our English readers who are conversant with the Charters of the medical corporations are aware that a peculiar method of election of professors and examiners is enjoined by the Charter of the Irish College of Surgeons, the function of choosing a fit person being devolved upon seven of the Council, who are cast upon by the turning of a lottery-box. In the reference to the election of a Professor of Midwifery which appeared in our columns last week we give a detailed account of the method, and we avail ourselves of the opportunity thus afforded us to call attention to the subject, in the hope of mitigating in some degree the

vicious results of so objectionable a method of election. For proof that the method is objectionable, and that, in the long run, its results must be injurious to the College and its School, we appeal not only to experience of many elections, but also to our readers' judgment of a system which makes the appointment to the most important offices in the College a matter of lottery-tossing, and insures the operation of private and personal influences in their worst form. We do not for a moment infer, as regards any recent selections made by this method (and last of all, as regards the appointment of Dr. John Cronyn), that bad selections have been made, or that personal views have ruled the choice; but we aver without hesitation that the results of the lottery system have frequently completely reversed the anticipations which had been entertained by the Fellows at large, and that under its operation Professors and Examiners have been more than once chosen who would not have had a chance in an open election either by the Fellows or by the Council at large. With all the perversity which attends the run of luck in games of chance, this lottery system has not infrequently laid the elective function upon seven of the uncompromising friends of one candidate to the exclusion of those of another, and it is usually quite easy to anticipate with reasonable certainty the result of the election as soon as "the draw" is known. This element of chance was introduced into the method of election with the worthy object of defeating the canvassing system, but we say that, while it entirely failed in this intention, it has introduced into the choice of College officers a principle which has on one or other occasion vitiated and must again vitiate the selection, and thereby act most injuriously to the College.

We are aware that it is not in the power of College or Council to alter the principle of this system without a resort to the Government, which, at the present juncture, would be very injudicious; but it is in their power, we believe, to mitigate the evil by adhering in its simplicity to the method which the Charter enjoins.

Hitherto it has been the practice of the seven electors to retire to a secret chamber, and even amongst themselves to record a secret vote. The whole purpose of the previous practice of the College seems to have been to render discussion upon the merits of candidates useless—to make the elector impenetrable to reasonable persuasion—and to bury in the most secret places of his mind the conclusion he has arrived at, and the vote which he has given. We need hardly point out that if electors are entirely irresponsible for their vote, and even forbidden to listen to free discussion, they should be more than human if they were not in some instances swayed by private and personal considerations, which should have no place in a Professorial election.

At the recent meeting of the College, summoned to witness the election of a Professor of Midwifery, Dr. Jacob called the attention of the Fellows to this matter, and pointed out by an analysis of the Charters that the taking of the elective vote by ballot, as has been hitherto done, is totally illegal. He complained of the attempt at secrecy which the system inculcates, and declared his personal experience that, while that attempt had no good effect in protecting the voter (inasmuch as the pledge of mutual confidence was habitually broken), it had, nevertheless, a most in-

jurious effect upon the selection of the candidate on the ground of simple merit.

We go further now than Dr. Jacob then went, and we submit that the intention of the Charter is that the seven electors should discharge their functions in the face of the College. We have found neither Charter, nor Bye-law, nor Ordinance to justify or render legal a secret vote; and we submit that until such legal authority is forthcoming it is not competent for the Council to continue to impose upon the College the extraordinary method of election which has hitherto been pursued.

Finally, we would ask upon what principle certain members of the Council are permitted to absent themselves from elections, and thus escape the onerous responsibility of their elective duty? and we would furthermore be glad to learn whether the fine which the bye-laws impose upon these gentlemen is uniformly enforced?

Notes on Current Topics.

Over Darwen.

DURING the last quarter of 1874 no less than 127 deaths occurred in Over Darwen from enteric fever. In September, it seems, a case of typhoid fever was brought into the town, into a house in the outskirts. The drain from this house emptied into the adjoining fields, through which the main which supplies water to the town passes, and thus the water-supply became contaminated.

Hospital Sunday in Liverpool.

THE collection made in Liverpool the Sunday before last for the hospitals resulted in £8,000. There are 600,000 inhabitants in Liverpool, and hence this subscription is considerably greater than that made in London, thus giving £30,000, in proportion to the number of the inhabitants.

Papillomatous Tumour of the Tongue.

MR. WAGSTAFFE exhibited at the Pathological Society of London, on the 19th January, two specimens of this disease, with drawings and microscopical sections. The first was from the tongue of a child aged 3 years, where a lump had been seen since the child was six months old, and it was said to have come after a fall. Twelve months ago, when first seen, there was a papillary growth on the dorsum linguae, commencing at one and a-half inches from the tip, and extending backwards for about an inch, projecting a quarter of an inch from the surface. After admission, the child's respiration became embarrassed, and the growth was removed on the 17th September, 1874. Microscopic examination showed the growth to be composed of highly hypertrophied papillae. Internally there were cavities showing like œvoid growth.

In the second case, the man was 50 years old, and there was a doubt as to whether the tumour was papillomatous or epithelioma. The growth was removed by the galvanic écraseur with a portion of the tongue. About 22 years ago the patient first noticed some white patches

on the tongue, of a warty character, which increased in size until this formed a sort of nodulated cauliflower mass on the surface of the tongue. In 1868 he was seen by Mr. Jonathan Hutchinson, who considered the disease as probably of syphilitic origin. He destroyed it, but it grew again, and formed a cauliflower mass, like a true papilloma, without ulceration or any discharge. The sub-maxillary lymphatic glands on the right side were greatly enlarged, but seceded after the operation, and the growth had not returned. The growth involved the right side of the tongue from the tip for about 3" back. The rest of the tongue was fissured and indurated. Under the microscope was seen great hypertrophy of the papillae but no invasion of the submucous layer.

Medico-Political Prospects.

THE meeting of the Executive Committee of the Medical Council has just concluded, and the business before them has, we understand, been of simple routine. No date has been fixed for the general meeting of the Council and it is probable that no meeting will be held until late in the session, unless there should be parliamentary business to discuss. We have reason to believe that the medical reformers of the British Medical Association are in hot incubation of a Bill which will be brought into the House of Commons at an early date, but they are not anxious that their occupation or intention should be known. The Bill—if there be one—will, of course, provide, as its first cause, for direct representation in the Medical Council, and it will, no doubt, exact a compulsory conjoint examination scheme for the three kingdoms. Such a bill would occupy a much better position now than it did on a former occasion, and might very possibly become law without serious opposition if it were not too radical in tone.

The visitations of the Medical Council at Oxford have already come off, and there will be little for the visitors to say. The medical licensing of the University is homœopathic in quantity, but first-rate in quality, and if it does little towards contributing to the *personnel* of the profession it does a great deal towards keeping up a high standard of education. We believe, however, that the expenses of this year's visitations have frightened the Executive Committee out of their propriety, and that the entire series will cost nearly £1,500. The London College of Surgeons has its "enabling" Bill ready, and all looks promising for a medico-educational reform of some sort.

Medical Advertising.

MR. JAMES LANE, in an address to the Harveian Society, on January 7th, alludes to the frequent custom of advertising medical books of all descriptions in the *Times* and other daily newspapers. Mr. Lane says he has himself never written a book, a fortunate thing for him to be able to say in days in which the struggle for professional existence is so great as to force even the most disinclined for literary labours to take up the pen. Mr. James Lane has, however, written many, very many papers in medical journals, any of which he could have published separately, and thus written a book, had he felt inclined. After all, what is this idea of non-advertising of medical works rather

a sentimental one in this commercial and hap-hazard England, where all hospital and other appointments are made by favour on family connection. Mr. Lane must remember that he had a famous father, and so did not require to write a book or advertise himself. And so we could speak of many other arguments.

Small-pox in Jersey.

THE deaths from variola in the town of St. Helier's were no less than forty during the first sixteen days of this month. Some of the cases were very malignant. A Vaccination Bill, making vaccination compulsory, has been submitted to the Local Government of Jersey by Dr. Le Cronier. Great precautions are being taken in Guernsey to isolate any cases of the disease that may be imported into that pleasant island.

Lady Doctors.

MISS MARIA VOGTHU, M.D., who was lately passed at Zurich, after most brilliant examinations, has established herself in that city as physician of women and children, and has already a large practice. She has married Dr. Henin, one of the professors of medicine of the Zurich Academy. It is curious to remark that all these lady doctors possess a great power of fascinating the hearts of our able and susceptible *confrères* both on the Continent and in the United States.

Buxton Sanitary Improvements.

It appears that Buxton is likely to become the seat of a series of experiments in the matter of disinfection and utilisation of the contents of the sewers, a point, as all know, of the greatest difficulty to carry out, however desirable the end to be attained may be. In the *High Peak News* of January 16 there is a well-written account of the system carried out at Leicester, Bilston, Coventry, and Leamington, from which it appears that the dry flow of sewage at Bilston is about 300,000 gallons a day, the population being 25,000. At Coventry, with a population of 40,000, the dry weather flow is about 1,800,000 gallons daily, there being a large number of water-closets in the town. The expenses of the disinfection of the sewage are not great, and it is to be hoped that the grand desideratum of utilising sewage may ere long be attained.

Longevity of Brain-workers.

DR. GEORGE BEARD (*New York Medical Record*, Dec. 15) says that brain-work is essentially healthful, and that brain-workers have less worry and more comfort and happiness than muscle-workers. To the happy brain-worker life is a long vacation; while the muscle-worker often finds no joy in his daily toil, and very little in the intervals. Physicians, lawyers, clergymen, orators, literati, and merchants, when successful, are happy in their work, without reference to the reward; and continue to work in their special callings long after the necessity has ceased. Where is the hod-carrier who finds joy in going up and down a ladder? and from the foundation of the globe until now, how many have been known to persist in ditch-digging, or sewer-laying, or any mechanical or manual calling whatsoever after the attainment of independence?

Good fortune gives good health. Nearly all the money of the world is in the hands of the brain-workers; to many, in moderate amounts, it is essential to life, and in large or comfortable amount it favours long life. Longevity is the daughter of luxury. Of the many elements that make up happiness, mental organisation, physical health, fancy, friends and money—the last is, for the average man, greater than any other, except the first. Loss of money costs more lives than the loss of friends, for it is easier to find a friend than a fortune. Almost all muscle-workers are born, live, and die poor. To live on the slippery path that lies between extreme poverty on the one hand, and the gulf of starvation on the other; to take continual thought of to-morrow, without any good result of that thought; to feel each anxious hour that the dreary treadmill by which we secure the means of subsistence for a hungry household may, without warning, be closed by any number of forces, over which one has no control; to double and treble all the horrors of want and pain, by anticipation and ruination—such is the life of the muscle-working classes of modern civilised society; and when we add to this the cankering annoyance that arises from the envying of the fortunate brain-worker who lives in ease before his eyes, we marvel not that he dies young, but rather that he lives at all. This is all true enough; but there is something deeper than this. Poor people die earlier than rich.

Unpaid Medical Services.

THERE is a good article in this month's *British and Foreign Medico-Chirurgical Review* on medical charity, in which the author sums up the numerous evils which have long been known to exist in our hospitals in London. "The advantages in the way of experience and reputation derived from a connection with public hospitals are constantly being urged, but such advantages afford no adequate repayment for the performance of arduous, continuous, and responsible duties, and they frequently fail, in the case of men of first-rate respectability and long hospital service, to bring about any reward in the shape of remunerative private practice." This is all quite true; but will the profession move? Alas! we are a sleepy set of men, and wedded to tradition. The Parisian medical men are more sensible, and all hospital appointments have an honorarium and are obtained by open competition. What says John Bull to such fair play?

Paisley and Glasgow Death-rate.

PAISLEY, a town of some 50,000 inhabitants, seems quite as unhealthy as Glasgow or Liverpool. It is abominably drained; over-crowding abounds. The death-rate actually was 65 in 1,000 a week or two back.

The Destitution of Liverpool.

MR. WORSNUP, a gentleman who has been engaged for three weeks in getting information on the wage-getting classes of that town, reports as follows:—

"The tenants of certain streets are chiefly dock, brick-layer's, plasterer's, mason's, and contractor's labourers, and cotton and corn porters, and, as a rule, only occupy one room, which has to answer as living and sleeping accommodation for the man, wife, and his family, and this

presents the most wretched state of poverty and dirt. Mondays, and often Tuesdays, are spent in drunkenness and riot. It is no unusual thing to see these people, before six o'clock on a Monday morning, crowding around the pawn-shops waiting for them to open so as to raise money on clothes, or, in fact, on anything they can carry. As soon as this money is obtained, away they go to the public-house, and seldom leave it till all is spent."

When we read of such miseries as these, we may indeed be rather inclined to be sceptical as to the great progress which civilisation has made. At the lowest part of our society there is yet a mass of savagery and degradation terrible to contemplate. Who can cope with drunkenness, over-population, and want? Not assuredly the optimist, or the complacent follower of Darwin or H. Spencer. Sterner minds are required, and if want and misery are ever to be less with us, we must look our fate in the face and determine to discourage over-pullulation.

The New Poultrice.

GREAT interest has been excited in the Académie de Médecine (*Tribune Méd.*, Jan. 3) by a new cataplasm suggested by Dr. Lelièvre. It is made with the *Fucus crispus*, a very abundant sea-weed on our shore, which is reduced to a very thin sheet by compression. When a piece of this cataplasm is cut off and dipped in hot water it swells up and becomes gelatinous. The *Fucus crispus* has been long used in medicine as well for its anaesthetic qualities as for a small quantity of iodine it contains. Poultrices of linseed meal dirty the linen, and they are often too heavy. This poultrice of Lelièvre requires to be covered with oiled silk to prevent it becoming dry too soon. The price will doubtless be low, and the poultrice is praised by Chassaignac, Verneuil, and other able surgeons.

Sanitary Reform.

THE interest excited by the conference on sanitary reform recently held in Birmingham has suggested the establishment of a National Sanitary Association for the promotion of social science. It is proposed that the first annual meeting shall be held in Birmingham in the autumn of the present year, and that other large towns shall be visited in annual succession if the proposal meets with sufficient support. A local committee will be first formed, and then, a meeting of members having been called, an executive, representing all important districts, will be elected to consider the future business of the association.

London Water Supply.

MAJOR BOLTON states that during the month of December last the state of the water in the Thames was unusually bad. On the 8th December the river suddenly rose two feet seven inches, and became very turbid. From an examination of the books, it was found that this is the worst flood occurring on the Thames for the last three years. During this time the Chelsea Company was obliged to take in dirty water and distribute as much as would pass through their filter-beds, which was very turbid flood-water imperfectly filtered. The discolouration was caused by the chalk and clay and is difficult to remove by filtration, requiring subsidence before being filtered. The

East London Company have completed the extension of the constant system of supply in a considerable part of their densely peopled district, and possess such ample reservoirs that the supply is not affected by the floods. The Southwark and Vauxhall Company have completed the reservoirs at Nunhead, to contain 18 million gallons.

Metropolitan Board of Works.

THE Vestries of Hampstead and St. Pancras have presented memorials to the Board of Works on the subject of the Hospital for Infectious Diseases at Hampstead. The Board decided not to interfere in the matter, which will, it is said, come before Parliament in the ensuing session.

DR. A. E. SANSOM has been elected Honorary Fellow of the New York Medical Society.

THE question of the admission of women to degrees in Arts is to be brought before the Convocation of the University of London soon.

THE annual returns just received at the Mining Record Office show that 5,449 tons of arsenic were produced in England in the year 1873. More than a third of it came from the Devon Great Consols Mine.

THE sanitary condition of Oxford still continues very unsatisfactory. Erysipelas and sore-throat are frequent. The water-supply of Oxford is impure, and cesspools and bad drainage are common in that city.

DR. HANDSEL GRIFFITHS, who, as a contributor to therapeutic and pharmaceutical literature, already occupies a foremost position in the ranks of our profession, and whose communications to the MEDICAL PRESS AND CIRCULAR are amongst its most valuable contents, has just received a distinction, the more gratifying because it has been entirely unsought. He has been appointed a Corresponding Member of the Therapeutical Society of Paris, and will undoubtedly prove his worth in that capacity. Considering that Dr. Griffiths has neither friend, relative, nor acquaintance in France, he may justly esteem this recognition of his writings as a very high honour.

BEANDRETH, of pill and plaster celebrity, writes to the *Chemist and Druggist*, complaining that that journal has libelled him by stating that he sells only £30,000 worth of pills annually. He explains that such a statement cannot be true, inasmuch as he pays stamp duty to the American Government on very nearly four millions of boxes annually. This estimate says nothing of a very large unstamped export trade, nor of the sale of Alcock's plasters to the number of 35,000 gross, or considerably over five million. We would venture to propound a new problem for the consideration of those ingenious, if not very useful members of society who spend their time in calculating how far the Franco-German indemnity would stretch if paid in sovereigns, and the coins set edge to edge. Given the proportion to the whole population of the world of those persons who are in want of pills and plasters, and given the number of pill and plaster sellers who make

money by supplying them. If one patent medicine man sells four million of boxes of pills and five million of plasters, to find the relative proportion of fools and sensible persons on the face of the globe.

Literature.

THE DISEASES OF TROPICAL CLIMATES AND THEIR TREATMENT. (a)

WITH the exception of Martin and Morehead's volumes on "Tropical Diseases," there is no other work of any note by an English writer to which army and navy surgeons can readily refer. The present volume, by Dr. Horton—an African—is a welcome addition therefore, to the literature of tropical maladies, but we wish it to be understood by our readers that we consider the title inaccurate. It should have been the diseases of Africa and the West Indies, as the references to the diseases of East India and its native drugs are but very slight, and are alluded to in the same incidental manner that African diseases are by Martin in his work. The book is divided into three parts, the first giving an account of the litoral, malarial, and specific tropical fevers. The chapter on ague is a good *résumé* of the subject, and the treatment laid down, both therapeutical and hygienic, is judicious, as are also the chapters on marsh, remittent, and ardent fevers. Hæmogastric, or yellow fever, "the hurricane of the human frame," from Dr. Horton's long experience and his thorough acquaintance with the physical and medical climate of Western Africa for the last fifteen years, as he himself says, "continually living in the vortex of tropical diseases, and taking notes of all important cases," it will not surprise our readers to be informed that this is one of the best written and most interesting chapters in the whole work. The account of dengue fever is the least satisfactory of the chapters in this part, in that it is incomplete, and no reference whatever is made to the more recently written papers on this subject by Indian medical officers.

The second part, on "Tropical Abdominal Diseases," treats, firstly, of intestinal, and secondly, of visceral diseases.

The first five chapters are devoted to indigestion, which is a clear account, and sufficient for all practical purposes. Constipation, as the author justly observes, "is a symptom in almost every case of tropical disease, and if correctly interpreted and treated, would tend to mitigate many very formidable complaints." This chapter evidences the author to be a good general practitioner, and the treatment, medical, mechanical, and dietetic can scarcely be improved upon. The article on dysentery is a good one, and the views of later writers are clearly marshalled forth and acknowledged. Dr. Horton is correct in saying "death from dysentery is now rather an exception than the rule, as it used to be a few years ago." The author describes dysentery under three different forms: 1. Acute; 2. Chronic; 3. Scorbutic, or asthenic; and after giving the symptoms of each, describes the pathology and morbid anatomy. The predisposing causes are next considered, and Dr. Horton is opposed to those writers on tropical dysentery who suppose that malaria is a common or direct and exciting cause of dysentery. Dr. Horton says, "Having for several years made this point a matter of careful study and investigation. . . . I cannot corroborate the opinion that malaria was a direct cause of dysentery, but it is one of the principal predisposing causes we have in tropical climates." After having care-

(a) "The Diseases of Tropical Climates and their Treatment." By J. A. B. Horton, M.D. Edin., F.R.C.S., Surgeon-Major of the Army Medical Department, &c., &c. London: J. and A. Churchill.

fully given all the predisposing causes, the exciting causes are given, and the author lays especial stress on "variations in temperature," and quotes very fully Dr. Massey's paper on "Acute Dysentery" in support of his views. The treatment of this disease is exceedingly well described, although it may be as well to mention, *en parenthèse*, that although "injections form one of the principal remedies of the natives in most parts of Africa, as well as other parts, for dysentery," such a remedy is regarded by the natives of India with abhorrence, and if it were used, it would be considered they had lost their caste. In "stubborn chronic cases," Dr. Horton says sulphur, in from fifteen to twenty-grain doses, combined with chalk and opium, is a most potent remedy.

There is a good deal in this chapter, as well as throughout the work generally, that shows a very earnest desire on the part of the author to weigh carefully the value of therapeutical treatment, and not as is noticed in many works lately issued, where treatment is indicated by merely giving a therapeutical index. We would suggest adding a fuller account of the hygiene of cholera in the next edition, especially as regards *campy*. In other respects we think the student will find the subject fully treated, and the history of the disease evidences an ability on the part of the author for accurate compilation such as we rarely meet with.

Liver diseases are next discussed, and then follows diseases of the spleen. Dr. Horton considers that of all local remedies for the reduction of the enlarged spleen the greatest benefit will be derived from the local application of the ointment of the biniodide of mercury, and quotes in support the opinion of Professor Maclean. Such practice, we may observe, is contrary to the views of many Indian practitioners, who have always held the opinion that mercury is inadmissible, tending as it does to debilitating results.

The third part treats of constitutional disorders, including anæmia, beri-beri, chronic rheumatism, delirium tremens, sun-stroke, goitre, guinea-worm, yaws, and Barbadoes legs. These chapters are all of average merit with the exception of the one on sun-stroke, which is incomplete, as, indeed, are most essays that have been written on the subject. We refer especially to the hygiene of this disease, and the absence of all allusion to the characteristic features, course and termination of insanity caused by sun-stroke.

In our necessarily brief review we have but touched on the leading features of interest, leaving much which we heartily recommend our readers to learn for themselves, as being not only interesting of itself, but valuable, as exhibiting steady perseverance, observation, and research performed with undaunted fortitude in trying circumstances and in pestilential climates.

We are sorry to notice, in conclusion, that the work has been allowed to appear before the commonest mistakes in spelling, of which it is full, had been corrected.

Correspondence.

THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Lombe Atthill has published in the *MEDICAL PRESS* of the 6th inst. a letter in which he contradicts a previous statement published by myself and others in the *MEDICAL PRESS* of the 30th ult.

The passage in our letter on which Dr. Atthill comments is the following:—"The proposal at that time (*i.e.*, December, 1867) to create the order of Member was a change of front rendered necessary by the action of the British Medical Association in favour of the 'one portal' system."

Dr. Atthill says, "The foregoing statement is entirely incorrect;" and, "Indeed, it was impossible that the 'one portal' system could have influenced the Committee, seeing

that it was not brought forward till the autumn of 1869, the report of the Committee being dated December, 1867."

By this flat contradiction Dr. Atthill accuses me not only of falsehood, but of stupidity; for I stated what was not merely "incorrect," but "impossible."

Although I had a perfect recollection of the resolution passed by the British Medical Association in Dublin (1867), and renewed unanimously in Oxford (1868), and again in Leeds (1869), at all of which meetings I was present, and advocated the "one portal" and "direct representation" principles; yet I felt there was no use in meeting Dr. Atthill's contradiction by a simple negative, seeing the tone of infallibility in which Dr. Atthill's letter was couched. I therefore wrote to Dr. Edward Waters, Chairman of the "Medical Reform Committee" of the British Medical Association, asking him whether my recollection as to the preceding points was correct or not. I received from Dr. Waters this morning the enclosed letter:—

14 Nicholas Street, Chester,
15th January, 1875.

MY DEAR DR. HAUGHTON,—When the Association met in Dublin (1867) the Government had charge of the Bill embodying the "one portal." At Dublin the Association decided that "direct representation" of the profession in the General Medical Council must be embodied in the measure.

At Oxford (1868) this was again resolved on unanimously. At Leeds (1869) the "Direct Representation" Committee, as it had been previously termed, was changed into one of larger scope, which was styled the "Medical Reform Committee." You were, then and there, unanimously placed on that Committee, and have ever since been a highly valued member of it.

Hoping it may be in our power soon to meet, believe me,
Ever yours sincerely,

EDWARD WATERS.

Professor Haughton, M.D.

This letter of Dr. Waters, confirmatory of my own clear and positive recollection, fully disposes of Dr. Atthill's wild assertion that I stated what was "incorrect" and "impossible," for my statement was pure and simple fact.

It is said that "fools rush in where angels fear to tread;" and such may possibly be the case of Dr. Atthill, whose character for wisdom and infallibility will not stand higher after this attack upon me.

I take no notice of the second letter of your anonymous correspondent in the *MEDICAL PRESS* of the 6th inst., as I regard the man who conducts a controversy by means of anonymous letters imputing bad motives as closely allied to the class of "cowards and poisoners." However, it is natural, perhaps, that the trade of anonymous writers should be taken up by those who advocate the ballot in order that they may black-bean in the dark a candidate whom they "do not like," to use the expressive phrase recently employed by one of the most zealous advocates of secret voting.

I am, your obedient servant,

Trinity College, Dublin,
Jan. 18, 1875.

SAML. HAUGHTON.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Lyons's letter purports to be a reply to my strictures on the one signed by himself, Dr. Cruise, and Dr. Haughton; but in point of fact it is no reply. In my letter I said Dr. Lyons made a statement which was "entirely incorrect," namely, that "the proposal at that time (Dec. 1867) to create the order of Member was a change of front rendered necessary by the action of the British Medical Association in favour of the 'one portal' system," the fact being that the "one postal system," called by its projectors the "one faculty system," was not projected till after the Leeds meeting at the British Medical Association, in August, 1869, and the Bill founded on the petition in favour of the system transmitted to the Secretary of State for the Home Department in October of that year by Dr. Bell Fletcher, that is, just two years after I had unsuccessfully urged the College to institute the grade of Member, and which Bill called forth the opposition of the College, and was not introduced into Parliament till 1870. Dr. Lyons does not attempt to reply to this, and being unab to do so, proceeds to make another statement, which, I regret to say, is as incorrect as his former one. Dr.

Lyons says, referring to my statement that I drew up the report of the Committee, "this is true just so far as that Dr. Atthill, as the officer of the College, made a fair copy of the draft report." Dr. Lyons is well aware that I, while Registrar of the College, as also those gentlemen who have held that office since I resigned it in 1868, had, and have a clerk who makes a "fair copy" of all the proceedings, whether of the College or its Committee, when such is needed. Had I used the term "draw up the report" in the sense of copying it, imputed to me by Dr. Lyons, I would have been guilty of that which I condemn in others; but I repeat, "I drew up the report" in question; that duty devolved on me because I was the prime mover in the matter, and also because, after a brief discussion, the Committee were unanimous, and left it to me to draw up, and the report I drew up was approved of, with the addition of two or three words suggested by Dr. Haughton.

Dr. Lyons then proceeds to make a statement, if possible, more startling than either of the preceding ones, namely, "that some (of the Fellows) even contemplate the imposition of a stamp duty" on the admission of Licentiates to the Membership.

To explain this strange statement I am forced to the conclusion that Dr. Lyons must be ignorant of the fact that the power of taxes is vested solely in the House of Commons; but I do not believe that any other Fellow of the College is ignorant of that fact: and I trust Dr. Lyons will pardon me for saying that I think he must have allowed some knowing "old Fellow" to play on his credulity. Why, instead of seeking to have tax duty imposed on its members, the College has actually more than once urged Government to remove the duty levied by it off Licentiates admitted to the Fellowship. I cannot tell what may have been said to my evidently credulous friend, Dr. Lyons, in private conversation relative to "the considerable fee" which would be imposed on Licentiates admitted to the Membership; but when the subject has been mentioned to me, and I have spoken on it to most of the Fellows, the opinion invariably expressed was that all Licentiates admitted before the grade of Member was established should be eligible to that grade either without the payment of any fee, or if any, of a nominal one.

It is much to be regretted that the attempt of the College to obtain for its Licentiates a title and rank similar to that obtainable by Licentiates of the Colleges of Physicians of London and Edinburgh should be turned to account to make a kind of political capital; but I have great confidence in the Licentiates of the College, and in the members of my profession at large. I believe them to be quite capable of judging for themselves who are the persons most sincerely desirous of elevating them and upholding the dignity of the College, and, to quote the language of the author, to whom the epithets "ignorant," "disingenuous," "deficient in candour," found in the letter signed by Dr. Lyons, and inserted in the MEDICAL PRESS AND CIRCULAR for the 30th ult., are applicable.

I am, &c.,

LONGB ATTHILL.

January 22nd, 1875.

THE ARCTIC EXPEDITION AND ALCOHOL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Recent Debates upon Alcohol," in your issue of Jan. 20, brought most vividly to my mind the vast importance of the subject as connected with the Arctic Expedition now getting ready for exploration in the Polar Seas. The experience of past expeditions of a like character seems to point to the necessity of excluding alcohol in any form from the rations to be issued to the crews during their engagement in the proposed voyage. Writing from memory, I would refer to the Expedition conducted by (I think) Sir John Kane. So long a time has elapsed since that period, and my not having the published account of the voyage in my possession, I can only state generally that no alcoholic drinks were issued to the men composing the crews of the ships during the whole time of their absence from England; and that no preceding expedition ever returned to England without loss of life from the severity of the climate, rum rations, however, having been issued to the men, in accordance with old regulations guided by tradition. When Sir John Kane returned from his arduous duties he brought the whole of his crews back—not a single man was lost; but no rum or other alcoholic ration was used by them under his command. What other inference can be

drawn from these facts but that alcohol, and not extreme cold, caused the deaths which occurred in previous Arctic explorations? Is it necessary to pursue this subject further, or to allude to the fact that in Sir John's published account of the voyage, he attributed his immunity from disease and death to the non-alcoholic treatment enforced on board the ships constituting that expedition? Or need any mention be made of Sir Garnet Wolseley's Red River expedition, on which occasion 1,600 men marched from Montreal to their destination, accomplished their work, and came back again in good health (no lives having been sacrificed to a mistaken and baneful custom) without the use of that supposed "necessary" for any extra exertion or exposure to the rigours of climate—an alcoholic stimulant?

The late Ashantee war is another instance of the non-necessity of alcohol, but in a widely different climate and under widely different circumstances; thus apparently proving that alcohol is not required in any possible variation of temperature or in any part of the world.

In the light of experiences like these, it may perhaps be judicious to call the attention of those about to leave our shores for the North, as well as the authorities under whose control they are placed, to the vital importance of the question. If life and health are jeopardised, in the one case, and conserved in the opposite, no exertion should be deemed too great, or no discussion too "dry" to bring this great and pressing matter into the prominence it so well demands.

Of course the question of expense is of such secondary importance, no further allusion to it is requisite; but at a future period this too may well occupy increased attention at the Admiralty and War Office, as also in the Mercantile Marine.

Yours faithfully,

H. P. G.

58 Poland Street, W., London.

MIDWIVES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—As there is a craze on the subject of the great value of the above among Dublin medical practitioners, I would like to offer a caution to young medical men about settling down in country districts. The caution I would give them is not to introduce them into their districts if they can keep them out. I have good reasons for offering this suggestion. There is no class which more forcibly illustrates the truth of the old adage that "a little knowledge is a dangerous thing," for every day they are found in the fulness of their conceit retaining cases in their exclusive hands, and so usurping the place of doctors, which were never intended should be left to them. I have more than once been called subsequently to cases of ruptured perineum, &c., after midwives. The masters of your midwifery hospitals ought to give the usual certificates to these women accompanied by the condition of forfeiture of such certificate in the event of their usurping the functions of doctor as well as nurse, notice of such forfeiture to be published in a local paper. Dublin men don't understand country habits on this point. No one in the metropolis thinks of having a nurse without a doctor; but one only is deemed enough in the country among many classes. The truth is, the public don't understand their exact function, and confound them with full-blown female doctors. Could not Messrs. Johnson and Ringland devote a little time to enlighten the public as to their real sphere. These gentlemen certainly ought, since it is owing to them that so many fees are taken out of the pockets of many country practitioners.

A COUNTRY PRACTITIONER.

THE next evening meeting of the Pharmaceutical Society of Great Britain will be held on Wednesday evening, February 3, at half-past eight precisely. A discussion on "The Construction of an International Pharmacopœia, from the Pharmacist's Point of View," will be introduced by Mr. Sutton, one of the delegates to the recent International Pharmaceutical Congress.

M. CHEVREUL, the eminent French chemist, who is now eighty-eight years of age, has been promoted by Marshal MacMahon to the dignity of the Grand Cross of the Legion of Honour, in recognition of his services to science.

PRESSURE on our space this week compels us to postpone publication of our notices of Cameron's "Manual of Hygiene" and the "Manual of Public Health," recently published by Fannin and Co., of Dublin.

IMPORTANT DEPUTATION ON VIVISECTION.

A LARGE and influential deputation waited upon the President of the Royal Society for Prevention of Cruelty to Animals on Monday last, to present an address signed by nearly fifty Peers, several members of the medical profession, and other gentlemen and ladies of position, urging upon the Society the duty of introducing into Parliament a Bill to prevent the continuance of the practice of vivisection. The Earl of Harrowby, as President of the Society, thanked the deputation for the moderation of their language as well as for their zeal, and promised the subject should receive their earnest consideration.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

THE Quarterly Court of the Directors of the Society was held on the 13th inst., the President, Sir George Burrows, Bart., in the chair.

The Acting Treasurer stated that the grants to be made amounted to £1,236 10s., to be distributed among 58 widows and 17 children, and 3 children were to be relieved from the Copeland Fund.

The expenses of the quarter were £55 12s. 5d.

Three new members were proposed and elected.

The Christmas donation to the widows and orphans voted at the last Court had been given a few days before Christmas to 56 widows and 20 children—£5 to each widow, £2 to each child, and £5 to each of the 3 children on the Copeland Fund, amounting in all to £329.

The deaths of two widows receiving grants were announced, and two fresh applications from widows were admitted.

It was resolved that a Committee consisting of the President, Treasurers, and Secretary should be formed to draw up a circular, stating the advantages to be derived from joining the Society, to be sent to all members of the Profession residing within the limits of the London District Post and the County of Middlesex.

As no anniversary festival will be held this year, the benevolent friends of the charity are invited to send their donations to the Treasurer or Secretary.

Obituary.

ROBERT ADAMS.

ALTHOUGH there are surgeons of his own epoch who still survive Robert Adams, his death will nevertheless be looked upon as the final extinction of a most noteworthy generation of Irish surgeons; and, as he has passed from amongst us, so we must bid farewell to the times when the profession in Ireland wore its highest honours, numbering amongst its sons such men as Abraham Colles, Crampton, Cusack, Jacob, Wilmot, Carmichael, and others not less noted and respected. The connection of Mr. Adams with the profession dates as far back as 1815, when he received the licence of the Irish College of Surgeons as the apprentice of Stewart, the Surgeon-General of the day. His first professional connection was with Jervis Street Hospital, which, however, he shortly relinquished in favour of the Richmond, in which he succeeded Ephraim McDowel. At this time, and for some years subsequently, he had been connected with Kirby and Reade in the founding of the Peter Street School; but his attachment to the Richmond Hospital caused him, shortly after his appointment, to dis sever his connection with Peter Street, and with Carmichael and McDowel he became the founder of the

Richmond—now the Carmichael School. His character as a surgeon in Ireland needed no record; but he has left his mark upon surgical literature, not only by his contributions to the Dublin Hospital Reports and Todd's Cyclopædia, but by his noted work on Rheumatic Gout—perhaps the most valuable work on the subject in the English language.

He occupied during his long and brilliant career almost every position of honour which a surgeon could occupy, highest amongst which were repeated Presidencies of the College of Surgeons, the Regius Professorship in the University of Dublin, the Surgeoncy to the Queen in Ireland, and the office of Senator in the Queen's University.

Robert Adams possessed all the qualities for a great surgeon—much talent, constant industry, and an address calculated to inspire confidence in those who sought his advice, and he was necessarily a great and successful surgeon. His profession, though not admitted usually to a close intimacy with him, respected him, and were proud of his high surgical attainments, and though his interpretation of the ethical relations of medical men to each other was not beyond cavil, he has left behind him the memory at least of a talented and skilful surgeon and "an honest opinion."

FRANCIS L'ESTRANGE.

THE Irish medical profession last week lost a member who was perhaps as generally known among its members as any one of its number, and who was no more generally known than he was respected. Frank L'Estrange was a household word in the family of every professional man in Ireland, to whom it was familiarly known as the name of a brother whose time and skill were ever at their command with friendly and disinterested readiness. His help was never wanting in their personal need, and was with equal liberality given when they required it in their practice in cases in which his special experience often rendered it invaluable.

More than half a century has now elapsed since Francis L'Estrange, while an undergraduate in Trinity College, commenced his studies, under the auspices of Sir Philip Crampton, to whom he was apprenticed about the year 1821, and with whom he maintained a close and affectionate intimacy up to the close of the life of that eminent surgeon. From the earliest period of his professional career, Mr. L'Estrange showed a readiness of mechanical invention which influenced his friends to direct his attention to the special line upon which he entered immediately after he was admitted to the ranks of the profession as a Licentiate of the Royal College of Surgeons, and he continued to practise as a dentist up to the period of his retirement into private life, some three or four years since. He never ceased, however, to maintain his position as a scientific surgeon, becoming in due course a Fellow of the College of Surgeons and Licentiate of the King and Queen's College of Physicians. So desirous was he of asserting this connection that he obtained a commission as a surgeon of militia, and up to the time of his death was surgeon to the Antrim Artillery. When he undertook this duty he was at the height of a most successful practice in Dublin, but never failed to join his corps at training time, and found in the change of professional occupation a recreation from his more laborious daily work. To those who knew his kindly social nature we need not say that in his yearly sojourn with his regiment he was ever heartily welcomed by his military companions. In his special practice Mr. L'Estrange brought to the service of his patients a general medical and surgical knowledge, which raised dentistry in his hands far above the level of a mechanical art, while his fertility of invention and practical skill enabled him to contribute most usefully to the advancement of operative surgery. Among his contributions in that line were a tourniquet adapted to compress the femoral artery in cases of amputation of the limb near to the hip-joint. He also invented and patented a truss for inguinal hernia, which is still in extensive use, and claimed to be the first who applied the principle of the screw in the operation of lithotomy. Among his other inventions was a contrivance for reducing luxations, and an apparatus for treating fractures of the lower jaw. At an early period of his professional life Mr. L'Estrange recommended himself to the Viceroy of the day, the Marquis of Anglesea, by the construction of an artificial leg, which was used with advantage by that illustrious soldier.

Mr. L'Estrange did not long survive his retirement, although

his age and his apparent strength of constitution seemed to promise a longer life. During his seventy years, however, he made many friends and no enemies, and has passed away amid the regrets of a large and closely attached circle of social and professional intimates, whose number, we regret to say, is rapidly diminishing.

Royal College of Surgeons of England.—The following members were elected Fellows of the College at a meeting of the Council on the 14th inst:—

Lawford, Edward, M.D. Aberd., Leighton Buzzard.

Thomas, Benjamin, L.R.C.P. Edin., Llanelly.

The following gentlemen passed the required examination and received the diploma in Dental Surgery at a meeting of the Court of Examiners on the 15th inst:—

Atkinson, Jonathan O., Kendal.

Bayless, Henry M'Ford, Islington.

Cartwright, Alexander, M.R.C.S., Old Burlington Street.

Gill, Henry B., Arnold Terrace, London.

Henry, William F., Cornhill, London.

Keeling, George R., Epson.

Silvester, Simeon T., Croydon.

Wallis, Charles J., Pau, France.

Watson, David, Torquay.

The following gentlemen passed the primary examination in Anatomy and Physiology on the 19th and 20th inst:—

G. T. Congrave, C. James, S. Skerman, W. H. Crowther, and S. Arnott, King's College; W. W. Cuthbert, W. H. Webb, G. H. Cressey, and C. R. Hall, St. Bartholomew's Hospital; F. Y. Livy, W. J. Heslop, W. S. Merriman, and W. B. Taylor, Owens College, Manchester; W. F. Blake, J. Heelas, H. B. Carter, C. C. Claremont, W. J. Cobbin, R. G. E. Willows, P. Hookham, and R. J. Stokes, University College; A. E. Powell, E. H. Jacob, R. N. Fenwick, G. B. Longstaff, and C. R. Gillard, St. Thomas's Hospital; G. H. Snowden and G. A. Duke, St. Mary's Hospital; W. P. Biden, Charing Cross Hospital; J. Carey, London Hospital; J. R. Blaikie, Cambridge; W. A. Molson, E. G. Henderson, J. L. Ritchie, and R. A. Stevenson, M'Gill College, Toronto; R. Mercer, H. C. Proctor, J. S. Sangter, Leeds; F. Wilson and G. R. Moore, Newcastle-on-Tyne; R. Griffiths and C. T. Marks, Dublin; R. F. Godfrey, Montreal; John Todd, Guy's Hospital.

Of the 317 candidates admitted to the recent preliminary examination, 153 were successful for the Membership and 39 for the Fellowship of the College.

NOTICES TO CORRESPONDENTS.

MR. STANTON, Oxford.—The number is out of print, and cannot be had at any price.

A CONSOLATION FOR DISAPPOINTED AUTHORS.—It must be admitted that authors, especially if they are inexperienced, or have no friends on the press, are not infrequently the subjects of unfair or harsh treatment. A little weakness of style, or some petty mistake is rushed out by the reviewer, and the unlucky wight pounced down upon in one journal or other, and lashed as unmercifully as if he had committed some foul crime, whilst the productions of other pens are ignored altogether, and the book upon which they had set their hearts, and from which they vainly hoped a great reputation would follow, receive but the scant publicity of the bookseller's shelves. For each or both of these classes a satisfactory solution has been arrived at. A letter and circular has been placed in our hands by our publishers to the effect that, on the 1st of February a Mr. Stonehan, publisher in Cheapside, will issue a new publication, entitled, "The Bookbuyer," in which "twenty pages of advertisements will be inserted, each page to consist of two-thirds of advertisement matter and one-third notices of your books, which you can supply." What finer opportunity can present itself to the eye of the disappointed author! Here, to the right of the page, myriads of anxious readers will be greedily taking in all that the author says in review of his own book, whilst to the left an advertisement of its cost, and the publisher, will point them to the exact spot where the precious treasure can be bought. Bravo, Mr. Stonehan! we shall be glad to receive the first number of "The Bookbuyer."

LECTURES ON HOMŒOPATHY.—Notice is given by advertisement in our columns and those of our contemporaries that a course of lectures will be commenced on Thursday, the 4th prox., in the London Homœopathic Hospital, by some of the leading men of that "persuasion," the attention of allopaths being particularly requested. Should any of our readers desire to hear what homœopathy really is the opportunity is offered them on presentation of their cards.

VACANCIES.

Royal Hospital for Diseases of the Chest, City Road. Physician. Honorary. Applications, with Testimonials, to be forwarded to the Secretary. (See Advt.)

University College Hospital. Resident Medical Officer. Full information from Mr. Robson, Secretary to the Council.

Birmingham Free Hospital for Sick Children. Two Acting Physicians. Emolument, £20 per annum; attendance three days per week. Applications to be sent in to the Medical Committee not later than the 31st prox.

Bath Royal United Hospital. Resident Medical Officer. Salary, £100 per annum, with board and residence. Application to the Secretary.

Hull General Infirmary. Dispenser. Salary, £100 to a fully qualified man. Applications to the Chairman of Committee.

St. Mary's Hospital, Paddington. Medical Tutor in the School. Full information of the Dean.

North Wales Counties Lunatic Asylum. Assistant Medical Officer. Salary, £100, with board and furnished apartments. Testimonials to the Clerk to the Visitors, Denbigh.

APPOINTMENTS.

BARBER, O., L.R.C.P.L., M.R.C.S.E., Demonstrator of Anatomy at the Sheffield School of Medicine.

BLAKELY, S., M.D., Superintendent Medical Officer of Health and Sanitary Officer for the Clogher Rural Sanitary District.

BROCK, W. J., M.B., Resident Medical Assistant at the Royal Infirmary, Dundee.

BURTONSHAW, T., L.S.A., House Surgeon to the North-Eastern Hospital for Children, Hackney Road.

CEURCH, W. S., M.D., F.R.C.P., a Physician to St. Bartholomew's Hospital.

COLL, R. M., L.R.C.P.L., M.R.C.S.E., Assistant Surgeon to the Gloucester Infirmary, Dr. FISKE R., Waterford, Superintendent of the Waterford District Lunatic Asylum, vice Dr. V. R. Fletcher, promoted.

COUPLAND, S., M.D., Curator of the Museum of the Middlesex Hospital.

CRAYEN, R. M., L.R.C.P., Resident Surgeon at the Workshop Dispensary.

CROFTS, J., L.K.Q.C.P.I., F.R.C.S.I., Professor of Midwifery at the Royal College of Surgeons, Ireland.

DAVIES, E., M.R.C.S.E., Medical Officer of Health for the Swansea Urban and Port Sanitary Districts.

DUNLOP, W., L.R.C.P.Ed., Superintendent Medical Officer of Health for the Letterkenny Rural Sanitary District.

GILL, S. A., M.R.C.S.E., L.R.C.P.Ed., L.F.P. & S. Glas., Medical Officer for the Torquay District of the Newton-Abbott Union.

LINGOAT, A., M.B., L.R.C.S.Ed., Medical Officer for the Morland District of the West Ward Union, Westmoreland.

LUCE, J. J., M.D., L.R.C.P.Ed., M.R.C.S.E., Medical Officer for the Welford District, and Medical Officer to the Workhouse of the Stratford-on-Avon Union.

MACNAMARA, RAWDON, F.R.C.S.I., M.D. (Hon. Causd) Univ. Dub.; Professor of Materia Medica, Member of Council, and Ex-President, Royal College of Surgeons in Ireland; Surgeon to the Meath Hospital, &c. has been reappointed the Representative of the Royal College of Surgeons in Ireland for the ensuing year upon the General Council of Medical Education and Registration of the United Kingdom.

M'BRIDE, C., M.D., Medical Officer for the Parish of Wigtown.

POWELL, E., M.R.C.S.E., second Assistant Medical Officer at the Essex Lunatic Asylum, Brentwood.

PURCELL, R., L.A.H.Dub., Apothecary to the Workhouse and the Croom Dispensary of the Croom Union, co. Limerick.

ROBERTSON, J. D., M.D., L.R.C.S.Ed., Medical Officer for the Eamont-Bridge District of the West Ward Union, Westmoreland.

SHEFFIELD, R. L., F.R.C.S.Ed., M.R.C.S.E., Assistant Surgeon to the Orthopaedic Hospital, Hatton Garden.

TAYLOR, J., L.R.C.P.Ed., M.R.C.S.E., Medical Officer of Health for the Whitby Urban Sanitary District.

THOMPSON, H. G., L.K.Q.C.P.I., L.R.C.S.I., Resident Medical Officer at the Western Dispensary, Broadway, Westminster.

WADDY, H. E., L.R.C.F.L., a Surgeon to the Gloucester Infirmary.

WALSH, D., L.K.Q.C.P.I., L.R.C.P.Ed., a Medical Officer to the Poplar and Stepney Sick Asylum, Bromley.

ARMY MEDICAL DEPARTMENT.—Surgeon-Major J. Fyrrer, C.S.I., Bengal Army, to be Deputy Surgeon-General. Surgeon-Major A. L. Adams, M.D., to have the honorary rank of Deputy Surgeon-General on retiring upon half-pay. Surgeon-Major E. Parsonage, M.D., retires upon temporary half-pay; Surgeon-Major A. L. Adams, M.D., retires upon half-pay; Surgeon W. G. Martelli and Surgeon J. V. T. Malcolm, M.D., retire upon temporary half-pay. Surgeon O. Codrington to be Surgeon-Major, vice T. J. Tufnell, retired on half-pay.

Marriages.

ARBuckle—BASSETT.—On the 19th inst., at St. Andrew's Church, Nottingham, Hugh Wight Arbuckle, M.D., of Thorne, Doncaster, to Martha Elizabeth Bassett, eldest daughter of the late Richard Bassett, of Mapperley Road, Nottingham.

SCATLIF—HARRIS.—On the 14th inst., at St. Saviour's Church, Haverstock Hill, J. M. Elborough Scatliff, M.B., C.M., M.R.C.S.E., of Brighton, to Edith, only daughter of the late Jas. Harris, Esq., of London.

SHIPLEY—NEVILLE.—At the residence of the bride's father, Edward Shipley, M.D., son of Thomas Shipley, Esq., Cape Clear, to Minnie Agnes, daughter of Thomas Neville, Esq., Ballintraana House, Macroom.

Deaths.

BOURNES.—On the 16th Jan., at his residence, Killala, co. Mayo, Wm. Henry Bournes, M.D.

BRACEY.—On the 13th Jan., Chas. Bracey, M.R.C.S.E., of Bristol Street, Birmingham, aged 60.

DUDLEY.—On the 9th Jan., at Yardley-Hastings, Northampton, Edward Dudley, M.R.C.S.E., aged 40.

HEALEY.—On the 9th Jan., Edward Healey, M.R.C.S.E., of Lister Street, Hull, aged 59.

JUSTICE.—At Mallow, Thomas H. Justice, M.D., of the North Cork Rifles.

M'LEAK.—On the 16th Jan., at Dublin, Annie, wife of J. D. M'Leak, Surgeon-General and principal Medical Officer in Ireland.

PICKFORD.—On the 18th Jan., J. H. Pickford, M.D., of Cavendish Place, Brighton, aged 78.

INDIAN MEDICAL SERVICES.

NOTICE is HEREBY GIVEN, that an EXAMINATION OF CANDIDATES for Twenty Appointments as Surgeon in Her Majesty's Indian Medical Service will be held on the 15th February, 1-75, and following days.

Copies of the Regulations for the Examination, together with information regarding Pay and Retiring Allowances of India Medical Officers, may be obtained on application at the Military Department, India Office, London, S. W.

The necessary certificates must be submitted to the Military Secretary at least a fortnight before the date fixed for examination.

(Signed) T. T. PEARS, Major-General,
Military Secretary.

India Office, 7th January, 1875.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—

Notice is hereby given that on Thursday, the 4th day of February next, at the hour of One o'Clock p.m., the President, Vice-President, and Council will proceed, according to the provisions of the Supplemental Charter, to elect an EXAMINEE in MIDWIFERY, in room of Dr. Cronyn, resigned.

A meeting of the Fellows of the College will be held same day, between the hours of One and Three o'Clock, to elect a MEMBER OF COUNCIL, in room of the late Dr. Adams.

Candidates are requested to lodge their applications and names with the Registrar at the College on or before Monday, the 1st day of February.

By order, JOHN BRENNEN, Registrar.

DUBLIN INFIRMARY for DISEASES of the EYE and EAR, Ely Place.

Ophthalmic and Aural Surgeon:

ARCHIBALD HAMILTON JACOB, M.D. Dub., F.R.C.S., Ex-Ophthalmic and Aural Surgeon to the City of Dublin Hospital.

Consulting Physician:

EVORY KENNEDY, M.D. (Hon. Caus.) T.C.D. and Edin., Fellow and Ex-President King and Queen's College of Physicians.

Consulting Surgeon:

GEORGE H. PORTER, F.R.C.S.I.; M.Ch. T.C.D. (Hon. Caus.), Surgeon in Ordinary to Her Majesty the Queen in Ireland; Fellow and Ex-President, R.C.S.I.; Senior Surgeon to the Meath Hospital.

Obstetric Physician:

JOHN CRONYN, M.D., F.R.C.S., Examiner in Midwifery, Roy. Col. Surgeons; Ex-Assistant Physician Rotunda Hospital.

Work, Income, and Expenditure for Twelve Months, ending June 30, 1873.

Annual number of Dispensary patients
Number of visits paid by such patients	5,847
Number of patients within the Infirmary	124
Number of operations performed	163
Total gross expenditure per bed per annum	£37 15 0
Average expenditure per intern patient	1 10 6

The Infirmary is wholly dependent on private benefactions, and is in debt to the Medical Officer. SUBSCRIPTIONS ARE EARNESTLY SOLICITED

MIR. I. SANDHEIM,

Dentist,

16 STJFFOLK STREET,

DUBLIN.

N.B.—A Vacancy for a Pupil

Established 1848.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S.,
 &c. (Knox's Coll.), and Author of *VIA MEDICA*.

Has always upon his books a large number of desirable Investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

PRACTICES AND PARTNERSHIPS NOW OPEN for Negotiation (in addition to those advertised in Dr. Langley's List, which is sent post free on application).

Z 94. In a large town, with great scope for increase, a GOOD CLASS PRACTICE, yielding about £700 a year. There is an excellent residence, with stabling, &c. Rent £55.

Z 93. LONDON. OPEN SURGERY and RETAIL. Receipts £800 a year, nearly the whole derived from prescribing and retail. There is great scope for outdoor Practice. The shop is well fitted and stocked, and the house is situate in one of the best positions in the N. W. district.

Z 92. KENT. An OLD-ESTABLISHED PRACTICE for SALE. Receipts over £600 a year. The whole practice within a very narrow area. Appointments, £40; patients, good middle-class. The house is small, but convenient, contains eight rooms, and is held on lease at a very low rent. The Practice is chiefly in the suburbs of a large town, and there is considerable scope for increase.

Z 91. LONDON, N. W. EXCELLENT MIDDLE CLASS PRACTICE for TRANSFER. The receipts average nearly £1,000 a year. No midwifery under £1 la. Appointments about £50. There is an Open Surgery associated with the Practice, and from which upwards of £400 a year is derived in cash. The books are open to the strictest scrutiny, and the highest guarantees of *bona fides* can be given. The house is situate in a main thoroughfare, and within easy access of railway communication to all parts of London.

Z 90. PARTNERSHIP in a good COUNTRY PRACTICE in a pleasant and rich agricultural district in the home counties, and within 60 miles of London. In consequence of the death of the senior partner there is a vacancy for a doubly-qualified gentleman accustomed to good society. The practice is very old established, and the actual receipts during the last three years average upwards of £900. Previous to the illness of the late partner the receipts were £1,300, and could be raised to that amount again. The incoming partner would rank as senior, and would take two-thirds of the profits. Appointments yield nearly £200. There is no opposition. The residence is large and convenient, with gardens and meadow land. Rent £30.

Z 87. DERBYSHIRE. An OLD-ESTABLISHED PRACTICE, yielding £600 a year, for TRANSFER. Patients good middle-class. Usual midwifery fees from £1 la. to £2 2s.; about thirty-five cases a year. Appointments yield £150. House contains twelve rooms, with stabling, coach-house, large garden, green-house, and land. Incumbent retiring from practice. Premium, one year's purchase, part of which may be left on security.

LOCUM TENENS WANTED.—For fully-qualified gentlemen of experience and unexceptionable character, Dr. Langley can find constant employment on liberal terms. Apply PERSONALLY at 50 Lincoln's Inn Fields, as above.

CASE OF RAPID AMAUROSIS. (a)

By H. R. SWANZY, F.R.C.S.I.,

Ophthalmic and Aural Surgeon to the Adelaide Hospital, and National Eye and Ear Infirmary, Dublin.

The case which I have the honour of bringing under the notice of the Society this evening is not a triumph of diagnosis, but rather an example of how much we still have to learn in this respect, even in ophthalmology, which boasts (and rightly so) of such progress in late years. My reasons for thinking it worth occupying the time of the Society are, because the case seems to be a most instructive one, and because it has at least one point connected with it which even the autopsy has not explained, and which I venture to hope may obtain a satisfactory solution from some member present.

The patient, John Shea, was a labourer. He first came under my notice at the National Eye and Ear Infirmary on the 10th October, 1871. He was then 20 years of age. He died on the 18th December, 1874, so that the history of his case extends over a period of more than three years. Even if I cared to weary the members with a minute relation of the progress of the case, I could not do so, as the patient was an inmate of one or other of the Dublin Union workhouses, during most of the time, and that I saw him only occasionally, through the kindness of the medical gentlemen under whose care he happened

to be. When first applying at the Infirmary he said that he had been suffering from frontal headache for a month or so previously, and also that he felt light in the head when he stooped at his work. He began to complain of dimness of the left eye a week before presenting himself to me, and in the course of two days, or perhaps less, became quite blind of this eye. On examining it,

I found that he could not even distinguish a very bright light from complete darkness. For the last two or three days he said the sight of the right eye had been failing. Its vision was such that he could tell how many fingers I held up at a distance of 20 feet, but not further, and besides this, there was a complete defect in the field of vision below and to the outside, extending almost to the point of fixation. He had had no vomiting, and was perfectly clear in his intellect and memory. Percussion of the frontal region gave pain. He never had syphilis, or any severe illness. He was not habitually intemperate, but had occasionally been drunk. His urine was normal. The pupils were widely dilated. The heart and lungs were healthy.

On examination with the ophthalmoscope, I observed in each eye an indistinctness of the inner margin of the optic disc. This, if pathological, would indicate neuritis; but it was so slight that it might well have been physiological, and, accordingly, no conclusions could be drawn from it. On the next day he was admitted to the Infirmary as an intern patient, and I applied Heurteloup's artificial leech to the right temple, in the hope of averting the progress of the disease in this eye, under the supposition that it might be of an inflammatory nature. It was of no avail, for by next morning the right eye had become as blind as the left. I then repeated the Heurteloup, without any result, except that of lessening the headache. He was put on the iodide of potash internally. The pulse was normal. He perspired very much, while at the same time complaining of a sensation as of a cold wind blowing on his face. On the 18th October he was discharged, without any alteration in his condition having been effected. He continued to attend the extern department until the 8th November, when he was admitted to the South Dublin Union. On the 10th I noticed a slight paleness of the left optic disc, which I thought might indicate a commencing atrophy of the nerve. While in the South Union, he was under the care of Dr. Fitzgerald, and continued to take the iodide of potash combined with bromide of potash. On the 15th November, as he was walking in the hall with one of his fellow-inmates, he suddenly noticed that he could

The Surgical Society of Ireland, January 8. The full account will be found at page 97.

see his companion's cap with the right eye. For some days the vision of this eye continued to improve, until he was able to count fingers at 20 feet, as he had done when first he applied at the Infirmary. Still, it was little more than central vision that he recovered, for the field of vision remained very much contracted in every direction. The right pupil reacted now very actively to light. The left eye still remained sightless. Fourteen days after the return of vision to the right eye, sight returned also in the left, but in a more limited degree, and with a more contracted field than in his fellow. Notwithstanding the partial restoration of function which took place, it was remarkable that the optic nerves assumed more and more, each of them, the appearance of white atrophy. He continued now until the 1st February, 1872, without any marked change. On that day, after a previous stage of excitement, and having complained of excessive frontal headache, and vomited some bile, he became drowsy and stupid for some days. On recovering from this he was affected with right facial paralysis, and ptosis of the left eyelid; the tongue when protruded deviated to the right side. From the facial paralysis he gradually recovered, but the ptosis continued, and in the course of a few weeks became associated with ptosis of the right eyelid and paralysis of the other branches of the third on each side, and double paralysis of the sixth, and that each eye-ball was directed downwards and outwards. He got a little better of these paralyseæ, but never completely recovered from them. The patient remained in the South Dublin Union for about six months. He then lived with his parents for about two months, attending now and then at the extern department of the Infirmary. After this he entered the North Dublin Union, under the care of Dr. Rutherford Kirkpatrick, and continued there until his death. He became subject to slight epileptoid fits, which recurred every three or four weeks. The vision of the left eye became permanently extinct, and paralysis of the fifth nerve of the left side, attended with corneitis, came on late in the case. There was, otherwise, no change in the eye symptoms. He complained sometimes of a cough, for which Dr. Kirkpatrick used to prescribe. He became very much wasted, and latterly preferred to remain in bed. It is a remarkable feature in the case that six weeks before he died dry gangrene of the feet and lower half of each leg came on. This progressed until it ended in complete separation of the leg on the left side, and, if he had lived a day or two longer, a similar result must have followed on the opposite side. He preserved his mind up to the last. I saw him a fortnight before his death, and he recognised me perfectly well. On the 18th of last month he was seized with a violent epileptic fit, in which he died.

Dr. Yeo was so good as to make the post-mortem examination for me. The pleural cavity, where it corresponded to the lower and middle lobes of the lung on each side, was obliterated by adhesions. The lungs were œdematous and somewhat congested. The kidneys were slightly enlarged, the capsule being separable, the surface marbled, and the consistence flabby—in fact, incipient Bright's disease seemed to be present. I may mention that albumen had not been found in the urine during life. The other thoracic and abdominal viscera were healthy.

The cranium was then opened. On slitting up the dura mater over the lateral hemi-spheres of the brain, in the usual manner, it was found that the dura mater and pia mater were to a great extent adherent to each other. In some places they did not lie in close contact, but were separated by a layer of peculiar jelly-like exudation of a brownish colour. This was especially abundant over the left hemisphere, where it attained a thickness of about one-eighth of an inch. The difficulty of removing the brain was very great, as it was found that the meningitis extended also to the base of the skull, where the dura mater is normally so adherent to the bone. It was only by great care that Dr. Yeo succeeded in separating the adhesions between the dura and pia mater in this region,

so as to remove the brain with but slight injury to its structure. One could now see how extensive the inflammation of the dura mater had been, for the whole floor of the middle fossæ of the base of the skull, the posterior part of the anterior fossæ, the anterior part of the posterior fossæ, and the basilar process, were quite rough from exudation of lymph. Adherent to the inner surface of the dura mater, and disseminated over it, but apparently growing from the pia mater, were found circumscribed tumours varying in size and shape from that of a small bean to that of a convex lens such as cataract patients are obliged to wear, and larger. A few of these were imbedded in the grey matter of the hemispheres. A microscopic examination of the growths showed them to be fibro-sarcomata. The case was now, I think, shown to be one of disseminated fibro-sarcomata of the pia mater, causing extensive adhesive inflammation between the pia and dura mater. This inflammation extended to the base of the brain, and gave rise there to disease of the optic nerves and to paralysis of other cranial nerves. It should have been mentioned that no tumour, growth, or other disease could be found in any part of the brain, especially, none in the optic thalami or corpora quadrigemina. The arteries of the legs were examined, and found quite healthy.

The points which seems of greatest interest in this case are—1st. The difficulty of the diagnosis. The idea of meningitis at the base of the brain did no doubt suggest itself, but was abandoned again as being insufficient to account for some of the symptoms. By aid of it, it seemed difficult to account for the rapid blindness with little or no ophthalmoscopic signs in the commencement, and without any other head symptom than that of headache, which was not excessive. It was also not probable that a man of twenty years of age, with all the appearance of health, and who had never had any severe illness, especially syphilis, should be suddenly attacked with inflammation of the meninges. I now have little doubt but that the slight cloudiness which I observed at the margin of the disc when the patient first came to me was the sign of a descending neuritis, and if I ever had examined his eyes during health this would have been of great value as an aid in the diagnosis. I am aware that such slight haziness of the margin of the disc at one side is sometimes a physiological appearance, due to a great number of nerve fibres being crowded together at this point in passing over from the nerve to the retina, and I could not tell but that it might be the fact in this instance. Nor did the progress of the case speak for meningitis. The partial recovery of vision, in the absence of other symptoms, did not make meningitis probable. The fits might be caused by meningitis, but they might be due to some other irritation at the base of the brain, or to anæmia of the brain. The patient suffered only once from purposeless vomiting—that very common symptom of basilar disease. The last symptom of all made the case a greater enigma than before—namely, the gangrene of the legs and feet. By the light of the necropsy it is easy enough now to explain the blindness, paralysis of the cranial nerves, and epileptic seizures; but where to look for an explanation of the gangrene of the lower extremities I do not know. I trust, Sir, that I may obtain some information on this head to-night.

CASES OF NERVOUS AFFECTIONS OF THE THROAT.

By CLINTON WAGNER, M.D.,

Physician to the New York Throat Hospital; late Assistant in Dr. Prosser James's Clinic at the London Throat Hospital.

CASE I.—Hysterical aphonia, six months' duration, cured by two applications of electricity.

Miss E., aged 12 years, sent me for treatment by Dr. Hammond; complete aphonia.

Her father stated that, six months previously, she awakened one morning voiceless, although she had retired

the night before in good health. She was of a very nervous, excitable, timid temperament, which induced me to regard the aphonia as of hysterical origin.

Nitrate of silver on a sponge probang had been used frequently before she was brought to me, but without producing any good result.

A laryngoscopic examination revealed paralysis of the adductors. I applied the constant current to the vocal cords by means of Mackenzie's electrode. One application restored voice, but the power of modulation was lacking; the second application, made the following day, restored perfect voice.

At the present time (four months after treatment) she has had no return of the trouble.

CASE II.—Paralysis of left cord adductor, four years' standing, cured by five applications of electricity.

Mrs. R. K., aged 28 years, applied for treatment at the Metropolitan Throat Hospital. She stated that since a child of about twelve years of age she has had attacks of hoarseness. About four years ago she lost her voice, and since then has not been able to speak above a loud whisper. An examination with the laryngoscope showed paralysis of the adductor of the left cord. Upon attempted phonation, the cord did not come to the centre, and the capitulum santorini of the right arytenoid was drawn beyond the median line, and in front of the left arytenoid. Heart, lungs, and uterus seemed to be unaffected. Five applications of the interrupted current from a faradic battery restored voice.

Case III.—Dysphonia in scrofulous child.

M. L., aged 9 years, sent me for treatment by Dr. Herzog. This child was anemic, and very undersized for his age; of a strumous diathesis. His father informed me that several months previous he had first observed the affection of his voice. The little fellow spoke in a very hoarse tone, running into a shrill falsetto, with loss of power to modulate, and at times completely aphonic.

The laryngoscopic examination revealed imperfect action of the adductors of the left side, sufficient to interfere with the vibrations of the right, thus accounting for the falsetto pitch.

Quinine and iron were ordered internally, with inhalations of creasote. Electricity applied several times. His father was compelled to leave for his home in the West, and the little fellow was under my treatment for a few days only. The case is merely mentioned on account of the extreme youth of the patient, the youngest I have ever seen with paralysis of the vocal cords.

CASE IV.—Paralysis of tensors from overstraining the voice in singing.

Miss —, aged 28, consulted me July, 1873, at the suggestion of Dr. Marion Sims. She stated that three years ago, after an attack of acute inflammation of the throat, she experienced, while taking her music lessons, a peculiar dryness of the fauces and weakness of the voice as the lesson progressed. She complained to her teacher of the trouble, who, however, urged her to continue singing, insisted on her practising at least an hour daily, declaring that "exercise was all that her voice needed."

To quote her own language: "He was annoyed when I sang feebly, and said that my singing well at the commencement of the lesson was a proof that I could produce stronger tones if I would exert myself." At the end of nine months she could no longer trill, and felt that her throat was daily growing worse. She discontinued her lessons for nearly a year, and was treated during that period by frequent applications of caustics on a sponge probang. Considering herself cured, she accepted an engagement in a choir. For a short time she had but little difficulty in performing her part; but one day, upon being urged by the leader to make a greater effort, severe pain suddenly ensued in her throat, and she fainted. From that time all voice for singing was lost to her.

An examination with the laryngoscope discovered congestion of the vocal cords, with general hyperæmia of the

mucous membrane of the larynx. Both vocal cords were relaxed. Particularly was this observable upon attempting the middle and higher notes, when the level appearance of their plane seemed to be destroyed. The trouble in this case, as could be plainly seen, was in the muscles which give tonicity to the cords, brought about by overstraining in attempting to reach the higher notes, and also by too prolonged effort.

She was under my treatment many months. My first object was to relieve the local congestion. This was accomplished by applications of the milder astringents, perchlor. iron, zinc sulph., &c., with inhalations of the same, and the local use of medicated spray from compressed air. Later, the constant current was employed daily at first, and less frequently as the improvement became the more marked. Iron and quinine were given internally. In July she wrote me: "I have quite recovered my health. I can trill, and my voice has regained its power, strength, and sweetness."

CASE V.—Paralysis of left tensor, from same cause as Case IV. Mr. K., aged 27, a professional singer and leader of a church choir, was brought me for treatment by Dr. Frank Reynolds, U. S. A. Mr. K.'s voice is tenor, and before it became impaired, he could sing to B; he stated that for several months his voice had been failing him, and at the time of consulting me he had abandoned singing, and could scarcely maintain an ordinary conversation on account of the distress and pain using the voice occasioned him.

A laryngoscopic examination discovered a relaxed condition of both vocal cords, especially the left, which wavered upon phonation, and did not quite come to the centre; there was also a slight congestion of the cords, and a relaxed condition of the fauces. Astringents were at first employed to relieve the congestion, after which electricity was applied three times a week for three weeks.

Under date of Aug. 25th he writes me that he has quite recovered his voice, and sings as well as ever, without the slightest difficulty.

ON CATCHING COLD. (a)

By Dr. E. STIMES THOMPSON, F.R.C.P.

THIS is a matter on which most of us have some experience; though it will be new to know that a philosophical description of that unpleasant phenomenon is not "catching cold," but "losing heat," cold or catarrh being occasioned by loss of the natural heat of the body, whether abstracted by getting wet, sleeping in damp sheets, or being exposed to currents of cold air. In a normal condition we lose by insensible perspiration through the skin a quart of water every day. A sudden exposure to cold is liable to close the pores of the skin, inducing what is commonly called the "goose flesh" condition, and this quart of fluid not finding its natural outlet has to escape by the mucous membrane or inner skin of the body. In addition to continually giving off fluid there is a great deal of gas, which in a state of health also passes off through the skin, and it is the confinement of that gas which more especially gives rise to the phenomena which result from catching cold. It is the retention of that poisonous gas in the blood which gives rise to the characteristic feeling of lassitude, drowsiness, and feverishness, and were it not for the provision by which it also is able to eventually escape by the inner skin, the result would be poisoning and loss of life. The normal function of the mucous membrane is to secrete only the necessary lubricating materials; but when it has also to carry of the gas and fluid which ought to escape by the skin, every function of the body is disturbed. The first discomfort is the increased escape of fluid by the eyes, nose, and mouth, which ought to

(a) One of the lectures to the public during Lent Term at Gresham College.

pass insensibly through the skin ; but the consequences of the cessation of its action are also often manifested in rheumatic attacks, rheumatic fever implicating the heart and joints, sore throats, bronchial attacks, inflammation of the lungs, toothache, neuralgia, or derangement of the digestive organs, according to the predisposition of the person affected. While, worse still, active tubercular disease of the lungs is frequently set up by exposure to cold where predisposition to the disease exists. After a description of the symptoms and the pathological conditions induced by cold, Dr. Thompson passed on to the more interesting points of its prevention and cure. In regard to prevention, he deprecated too much fear of catching cold and the dread of the least exposure to cold air, as being very likely to bring about that tender hot-house plant condition so favourable to inducing the evil one wished to avoid. Exposure to cold air, he insisted, does no harm, except under the condition of its moving rapidly in a small space. Thus exposure to strong wind in the open air does no harm, while a Portuguese proverb said with a great deal of truth, if you catch cold from a draught through a keyhole you had better make your will. It was draughts coming with great rapidity through small openings which were so especially injurious. Living constantly in very impure air made people very sensitive to cold, and ill-ventilated bed-rooms had much to answer for in this respect. It was a mistake to suppose that night air, except in a quish place, was obnoxious. In London night air was purer than air in the day, and he advised every one, while avoiding a direct draught, to keep the bed-room window slightly opened. The effect of want of ventilation was strikingly illustrated in the case of horses. When left to run in the fields they were hardy, and did not suffer at all from cold ; but cooped up in warm stables they became very sensitive to cold and prone to serious and fatal affections of the chest. That was a lesson to us to keep our bed-rooms cool and well ventilated. In clothing, the great thing was to vary the character and amount according to the season and weather, avoiding the extremes of always being swathed in flannels no matter what the temperature ; or of never wearing flannel at all. As a rule we might imitate with advantage in cold weather the example of Russians and Canadians, who were careful to put on very warm outer clothing when leaving the house and to remove it the moment they came in. Of the curative treatment what was called the "dry method" had once been in great vogue. This consisted of abstaining from all fluids for 24, 36, or 48 hours, and where rigorously followed at the outset the cold was generally stopped. He would not, however, recommend this treatment to any but those in thoroughly good health, for in the delicate or the sickly the derangement of the vital organs, especially the liver and the digestive organs, by this abstinence from fluids, brought about evils more serious than the cold. Another method was the maintenance of an equable warm temperature, and where this could be done the skin was soon restored to a more natural condition, and the evil was relieved. The mucous lining, however, could be more rapidly relieved by inducing the skin to perspire vigorously, and if this was done at the outset the cold would be checked. This could be done by a hot bath ; or, very much better, by a Turkish bath, for while in a hot water bath it was not possible to endure a greater heat than 100 to 103 degrees, in a Turkish bath a temperature of 150 to 200 degrees could be sustained without discomfort. Vigorous perspiration was in this way induced, the blood was drawn from the internal organs to the surface, much of its impurity eliminated, and if the cold douche was avoided and the skin was got thoroughly to work the patient walked away in an hour, and left his cold behind. All these methods would only be successful in the early stage of cold. The medical treatment of cold also had for its object inducing action of the skin. Spirits, though they lowered instead of raised the temperature of the body when erroneously taken for warmth in cold weather, were admissible in

the form of a "night cap" for the treatment of cold. Mixed with hot water and nutmeg, spirits—rum especially—had great power of promoting perspiration, and therefore of relieving cold. The drugs having an analogous effect were ether, especially when taken in small and repeated doses of two drops to a teaspoonful of water every ten minutes ; opium, of which some people took half a teaspoonful, might produce a fatal effect. Sal volatile, or better still, sal-ammoniac, was a very useful remedy for cold, as it promoted a glow on the surface and relieved that influenza-like condition which was so exhausting.

HOME-WORK FOR THE MEDICAL MISSIONARY.

By EDWARD LANE, M.A., M.D. Edin.

(Continued from page 73.)

BUT it is in the case of the lower classes, where poverty is added to ignorance, that the baleful fruits of such an union are so terribly conspicuous. Enter one of the human dens—and it need not be among the worst—where, not a hundred yards from the Strand on one side, and Oxford Street on the other, a family, perhaps two or three, are huddled together, living very much like the beasts of the field. A picture revolting to every sense will meet your eye, utterly shocking in the midst of a civilised community. You will at once say, "that is the result of poverty ;" and to a great extent, so it is. But poverty is not all. Ignorance is rampant there too, of the direst and most abject kind, and most especially of the most elementary laws of physical well-being. Terrible, therefore, in its effects as the poverty is, in such fearful depths as it is there found, in debasing the moral character, its effects are tenfold intensified by the co-operation of ignorance, and it is absolutely certain that if anything could be done to remove that ignorance even a little, a marked change for the better would soon be manifest among the most indigent and apparently hopeless classes of the community. But the ignorant require to be taught, and this brings us back to the question, Who, under present circumstances, are best qualified to undertake the task ? I have already said that by far the most frequent and systematic labourers, hitherto, in the gloomy homes of misery and vice have been the clergy. But they have approached the work, only naturally, more from the moral and religious than the physical point of view, and in my opinion that is an error in the order of time, and one which fully accounts also for the comparatively small results accruing to reward efforts so great, so earnest, and long-continued. The fact is that the evils to be counteracted are both moral and material, but if you would have any success proportioned to your labour, you must begin with the latter. And that is precisely why I hold that, in the actual state of things, the teacher most wanted is the doctor. It is not, assuredly, that I would wish to see the clergyman estranged from the benevolent work which has engaged him so long and so worthily, nor is that necessary. There is ample room for both, and my contention is that the labours of the doctor will only prepare and pave the way for those of the clergyman. That was the idea, we may be sure, which prompted our great and lamented Livingstone, with characteristic Scotch sagacity, to superadd the doctor's education and calling to that of the clergyman, with which he had commenced, before he accounted himself qualified to undertake the missionary's part with success. He chose Africa for the field of his labours:—in my belief, a much more interesting and promising ground for similar efforts lies everywhere around us amid the "winds and closes" of all the great towns of our own England. Is the medical missionary, though he be not clergyman as well, really less needed here than there ?

And here, as a general proposition, it is surely not necessary to claim for the members of the medical

profession the credit of being much and most useful among the poor, as among the rich. Wherever disease is to be dealt with, and physical pain soothed, there, it is well known, is the doctor to be found unfailingly at his high calling. And let me ask in passing, how many have taken account of the spirit of daring and self-sacrifice—the silent heroism—that so often accompany him! I would not undervalue the courage of the soldier, titled or untitled, fighting his country's battles in the face of the enemy, with drums beating and colours flying; but I would ask if that of the doctor is not often greater, when, alone and unobserved, often too without the prospect of the smallest pecuniary reward, he enters the home of typhus and small-pox, or stands by the bed of his fellow-creature smitten with cholera? Surely humanity alone, and the highest sense of duty, can prompt that devoted courage, for no one is there to mark it—

“No fame is there to say who bleeds,
Nor honour's eye on daring deeds.”

But still, the point which I wish to urge is that the doctor is there in his capacity of *healer of diseases*, and in that only; and great and needful as that function may and always will be, in my idea it does not fill up the full round of a medical man's calling; nay, it is the least valuable by comparison, and the less important, of the services he is capable of rendering at present to his fellow-creatures. For mankind, be it observed, even in the most adverse of physical circumstances, are not always ailing, and therefore do not need the help of a physician as such; but the homes of the lowly are few where his daily presence in another and extended character—that of a *medical missionary* (so to speak)—would not be a boon of the highest value. To some, both in the medical profession itself and out of it, such an idea may appear fanciful or sentimental. In reality, it is but an enlarged view of a medical man's duties; but I am aware that the view is novel, and will have to be well considered before being accepted and acted on, as I trust it finally may be. I repeat, then, that the *cure* of diseases ought not, properly considered, to be the sole function of the doctor, but equally with this, and really much rather, their *prevention*. Here is a field of practical usefulness opened up to the medical calling, and especially to its younger members, of which it is impossible to overrate either the extent or the moral glory to be achieved in it. The work is there plainly enough, and the fittest labourers for the work are at hand too, in multitudes of only half-employed medical men; but the idea, to bear fruit, has to be taken up by the leaders of the profession, and the great truth proclaimed from the University chairs, that one of the prime functions and most solemn duties of the young practitioner, both from a scientific and humanitarian point of view, is to labour in the missionary spirit among the poor. As always happens, such a beneficent doctrine, if carried into practice, would be twice blessed. It would be of untellable value to the poor, a boon whose good fruits it is impossible to estimate adequately, but some of which would surely be greater cleanliness and temperance, with their legitimate consequences, less vice and less crime—in one word, an increase of health and morality. On the other hand, the medical profession, in its turn, must needs be benefited in more ways than one by such a movement. First of all, every one of its members joining in it must gain in personal nobility, from the consciousness of helping forward a great and pressing work in the spirit of pure manly duty and brotherly love. And then on the medical art itself the effect would probably be to accelerate the great change of medical opinion now going on in the profession as to the true scientific foundations of medicine, pointing out thereby practically, and in the most effective of all ways, that the prevention of disease should constitute the first and greatest aim of the medical man; one more in accordance with sound physiological reasoning and the dictates of common sense than has often prevailed hitherto; and thus leading up to the more sure establishing of the great doctrine of “hygienic medicine,” which is already producing

so beneficent a revolution in the general treatment of disease. And yet one final consideration—not the highest certainly, but one which the friends of the medical calling might well urge. It must often have occurred to many that, considering the varied and extended education of the medical man, and the great services he daily renders to society, a full recognition of such services on the part of the public has perhaps not always been apparent. The meeting, last autumn twelvemonths, of the Medical Association in London, with the exposition it afforded of the vast and laborious field of investigation in which the medical profession is everywhere engaged, struggling so patiently after nature's “open secret,” in the interests of the whole human race, must surely have been regarded with admiration. One earnest and eloquent voice at least, never raised but for the promotion of noble ends, in Parliament or out of it, was heard in generous praise of the doctor and his efforts; but it cannot be doubted that such additional services as I have pointed at, of such immense value to the general community, must necessarily command the grateful recognition (and with it the highest social consideration), of every properly constituted person of whom that community is composed.

Such, at any rate, are the views of the writer, very summarily expressed, on this great subject. Few, perhaps, will doubt the value of the idea, and none the importance of the work to be done. But some may yet ask: Is it possible, when regarded in the most matter-of-fact, practical way? Is it, to any large extent, within the power of the members of the medical profession to undertake the work? I sincerely believe it is. As before said, there is in all our large towns a whole army of only half-employed medical men—only half-employed because of the fixed notion, inherent both in the world and among themselves, that their sole occupation should be to cure disease—a part of whose spare time might be devoted with the very greatest advantage in labouring, as I have tried to explain, among the poor. But I do not disguise from myself the fact that, practicable though it be—easy indeed with a little organisation—it will never be done without a large infusion of what I have already called the missionary spirit. In the first place, the work must be partially gratuitous, for, in financial parlance, “it won't pay”—and with the increasing difficulty of earning a livelihood in this over-peopled old country, of course that is an obstacle. The doctor, too, must live by his profession, if it is worth following. But I repeat that, with but a moderate amount of organised arrangement, a certain amount of funds, possibly, being provided for the purpose by the public, and professional distinction and reward, whether in the form of hospital appointments or otherwise, being accorded by the Medical Faculty itself for good work done, some small portion of each day might be devoted to so great and pressing a duty—some of the many *leisure* hours only that belong to all but those in established private practice. The vital question is, Will the suggestion be taken up by the heads of the profession, and enforced with the authority that belongs to age, standing, and character? and still more, Will it come to be taught in the schools, as a great and sacred portion of every medical man's labours in the world—a duty which he owes alike to his profession and to mankind?

To myself, striving to look at the whole subject not only with the eye of a doctor, but also of a citizen of a great community, whose example goes for much in all the ongoinings of the world, I confess that the project we have been considering is peculiarly interesting and attractive. It is ever so far-reaching; and in contemplating it, one cannot but be struck with both its grandeur and goodness. Plainly, here is a door opened for the special exertions and services of the medical man, in his character of man of science and philanthropist no less—such services, moreover, as only he is qualified by education to render effectually. And surveying the world's condition as it is nearly everywhere, and unhappily not least in our own country, I cannot conceive a more glorious career of public usefulness, humanity, and devotion, than that to which, as it were extra-professionally, the medical profession would thus be sum-

moned. No one, indeed, can be more conscious than the writer that in the foregoing remarks a suggestion alone has been thrown out—the mere germ of a possibly great effort, not a completely thought-out and organised plan—yet even in its crudest state the bare idea may be worth something as a foundation to work on. Numbers, both in the profession and beyond it, who take an interest in social progress and are qualified to judge, will be in a position to pronounce how this may be; and in any case, the work to be done is of such a character that anyone in offering his mite of proposal in regard to it may be permitted to think, "*nec tentasse quidem est dedecus.*"

A Course of Lectures

ON THE

NATURE AND TREATMENT OF DEFORMITIES OF THE HUMAN BODY,

DELIVERED IN THE MEATH HOSPITAL, DUBLIN, BY
LAMBERT H. ORMSBY,

Surgeon to the Hospital, and Demonstrator in the School of Surgery
Royal College of Surgeons in Ireland.

LECTURE IX.

THE DEFORMITIES OF THE UPPER EXTREMITY.

Introduction—Deformities of the Shoulder: Causes, Treatment—Elbow-joint: Treatment for Stiff Elbow—The Wrist-joint: Various Bursal Tumours met with in the Situation—Various Congenital Dislocations—Cramps of Fingers peculiar to each Colling—Ganglions—Contracted Fingers—Stiff Joints—Webbed Fingers—Congenital Malformations.

DEFORMITIES OF THE SHOULDER-JOINT.

BEFORE considering in detail the deformities and changes that take place in this important articulation, which has, as before mentioned, the widest range of motion over any other joint in the body, it would be well to remember the shape and outline of the healthy shoulder, remembering how and what constitutes the rotundity and preserves the shape of the upper portion of the humerus, and, in fact, the precise anatomical bearings of the joint as regards the muscular attachments and the relative positions of the well-marked bony prominences that can be distinctly seen and felt in any healthy shoulder. Running your finger along the clavicle to its acromial end, then running your finger along the spine of the scapula, the position of the acromial process to the outer side is easily ascertained, then on the inner side of the ball of the shoulder the coracoid process is easily and distinctly felt. Just a little care in these anatomical points will prevent many a mistake that is constantly made in the diagnosing of obscure injuries about this joint. I shall divide the deformities met with in this situation under three heads—viz., Accident, Disease, and Debility.

From Accident.—After severe gun-shot or machinery accidents, or the contraction resulting from burns or scalds, or old unreduced dislocations, we frequently find great deformity, impairment, and limitation of motion. In some cases the arm may be united to the side after cicatrization has taken place, due to the non-use of the joint during the healing process; a certain amount of ankylosis has been induced; long unreduced and congenital dislocation may at times be met with.

Treatment.—After severe wounds, gun-shot or otherwise, the arm to be placed in a position less liable to be followed by impairment and derangement, and passive motion set up now and then at short intervals, as soon as possible. If there is much webbing of the arm to the side, this cicatrix must be cut through, and a mechanical instrument worn to keep the arm out from the side. Many devices are recommended, but all require various modifications to suit the circumstances of the case. If in old

unreduced dislocations, reduction ought to be effected, if possible, and also if reduction would likely give more motion and use to the arm. Dieffenbach relates two cases where he effected reduction—in the first case, after two years, by section of the pectoralis major, latissimus dorsi, teres major and minor muscles; the second case had existed many years.

From Disease.—The contour of the articulation is occasionally very much changed, and motion considerably impaired, when any of the tissues in or about this joint become diseased. Rheumatic swellings are often seen here, and after a repeated number of attacks leave a certain amount of chronic enlargement behind. The capsule in many cases is found greatly thickened. Chronic rheumatic arthritis is frequently met with in this situation, and causes great destruction to the component parts of the articulation. A very good pathological specimen of mine, presented to the Museum of the Royal College of Surgeons, Ireland, shows exactly the great change that takes place in the joint. The fibrous variety of ankylosis occasionally occurs here; but I may mention complete immobility of this joint is not common. True bony ankylosis I have never seen in this situation. Scrofulous and carious disease affecting this joint is very frequently seen. I have seen a "warty ulcer of Marjolin" implicating this articulation.

Treatment for the various forms of deformities caused by disease depends greatly on the primary affection—in some cases constitutional remedies, in others local applications have been deemed the most advisable. In rheumatic and gouty affections the vaunted remedies for those diseases ought to be administered, together with local anodyne ointments and liniments. In unreduced dislocations, passive motion and gymnastic exercise recommended, in order to give the person the greatest use in the impaired member as possible. The treatment for fibrous ankylosis, when no contra-indication exists, the adhesions should be broken up, and the same rules to be exactly followed out as mentioned when considering ankylosis in the lower extremity.

From Debility.—The various form of paralysis causing atrophy of the muscles and giving rise to what is termed *drop shoulder*, or inability to raise the arm, the deltoid muscle being the muscle most affected, together with the capsular and other ligaments connected with the joint, which become lax and impaired, so much so as to allow occasionally the head of the humerus to slip out of its natural cavity.

Treatment.—This depends greatly on the cause of the atrophy. A purely local treatment seems in some cases to be most efficacious, various forms of liniments, blistering, and galvanism of the muscles, passive motion set up by gymnastic exercise. Constitutionally, the debility should be treated by a course of strong tonic medicines, and every measure enforced that will ensure constant and healthful use of the debilitated muscles, for in many cases, owing to the disease, the muscles become considerably wasted and flaccid.

DEFORMITIES OF THE ELBOW-JOINT.

This articulation we very often find the subject of deformity, and, in fact, I may say it is more frequently affected than any other joint in the upper extremity, and for convenience I will divide them under two heads—1. Accident; and 2. Disease.

From Accident.—After fractures and violent strains in the vicinity of this joint, in some cases implicating the articulation itself, more or less stiffness or impairment is very likely to ensue, giving rise to what is termed *stiff elbow*. Now I know of no joint in the body where it is more important to be aware that a long-continued disuse from motion and the fore-arm kept in the one posture for the same length of time so frequently ends in impairment and partial stiffness and ankylosis. The contraction caused by the healing of very severe burns frequently produces a degree of deformity; and in fractures, healing of burns, or, in fact, during the healing of any traumatic injury about the joint, constant passive motion should be

often and constantly repeated at stated intervals, as any neglect will certainly be followed by stiffness or other still more unfortunate consequences. Mr. Hamilton, of America, as mentioned in another place, recommends passive motion to be practised seven days after fracture, implicating the joint, in the very young subject. This period, in my opinion, is rather early, and I would rather say a fortnight would be time enough to begin. Another point about the application of splints, and the position the fore-arm should be kept in during union of fractures, or in fact any injury about the joint. I may be deemed peculiar in differing from the usual way of applying an angular splint, and allowing the fore-arm to be flexed across the chest, and the arm bandaged to the side. No matter what way the arm is bent—to a position most agreeable and convenient to the patient's feelings, the muscles, biceps principally, are found to be in a state of semi-contraction, *i.e.*, shortened, which becomes permanent, producing stiffness and other deforming effects. I consider the best position is to have the arm *fully extended*, and kept in that position for a period which will vary according to the age of the patient; the muscles will be extended and stretched to their full extent, and if slight stiffness takes place flexion can easily be put in force, breaking up any adhesions, and preventing any risk of rupturing muscles, arteries, or nerves, which might occur if extension was practised suppose the arm is placed in the usual flexed position after fracture, or other injury. Old unreduced dislocations will necessarily produce considerable impairment, and in some cases ankylosis, as well as in fractures implicating the joint; for these unreduced dislocations in all cases, if there are reasonable grounds for suspecting an attempt at reduction would be successful, that attempt should unquestionably be made; but if a considerable time has elapsed, it is very doubtful whether reduction, if effected, would give the person very much more use of the arm. It is clearly laid down by authors that after certain periods have elapsed it is unwise to attempt reduction. Now, the periods named, in my opinion, are prone to mislead, for a dislocation in one subject, after a certain time has passed by, may be easily reduced, whereas in another person, when just the same time has passed, it may be exceedingly difficult; and different circumstances, variety of causes, and variety of patients, must in every case be considered, for a dislocation of three weeks' standing in one might be as difficult to reduce as that of three months' standing in another. In diagnosing and making out obscure injuries of this joint great attention should be paid to the anatomy of the part, and the relative positions of the bony prominences—*viz.*, the olecranon and internal and external condyles. Many a doubtful opinion given with caution might be changed into a moral certainty, and given with confidence and truth as regards the actual fracture injury, or otherwise, that has taken place if the anatomical bony points were more clearly known and made out beforehand. When the arm is extended completely, the internal condyle of the humerus, the olecranon process in the middle, and the external condyle to the outer side, is nearly found in a straight line; and I need hardly say in dislocation or fracture this relation will not be present, although in an occasional isolated case the relative position may be found but little changed. However, other signs of the particular injury will be likely present to enable you to clear up the matter. In all cases, when they are brought to you, make out these bony points, and remember their normal relations as regards each other. To the outer side of the olecranon, just below the external condyle, there is a very apparent pit, or hollow in the skin, constant and easily recognised in all arms, just below and behind the supinator radii longus. In the hollow you can easily feel the head of the radius rolling in the lesser sigmoid cavity, in supination and pronation, and on examining, it at once clears up the point whether the head of the radius is in the right place or not.

From Disease.—This is a most common cause of deformity in this joint, considering the many varieties of inflammation, specific or non-specific, that are prone to affect this joint, and always act most injuriously on the ginglymoid,

or hinge variety of articulation. Gout, rheumatism, gonorrhœa, syphilis, scrofula, or the consequence of traumatic synovitis, these all have the power of injuring, and at times producing complete immobility and ankylosis. In the Museum of the Royal College of Surgeons, Ireland, there are some beautiful pathological dry specimens, which were kindly shown to me by my friend Dr. Barker, the Curator, exhibiting the various degrees and forms of ankylosis, both of the false or fibrous variety, as well as the true and bony fusion of parts, with complete obliteration of the articulation. There are two specimens which particularly claim the attention of those interested in true ankylosis, which were presented to the museum by Dr. Handzel Griffiths. They show very clearly true bony fusion in both elbow-joints; the radius is absent in both cases, but the ulna is found completely welded and grown into the humerus, and ankylosed at right angles to the respective bones. No appearance of disease is present; the bones are of a full adult size, and this change must have commenced at a very early date; but nothing could persuade me that it was, or ever could be, congenital. Unfortunately, like many other cases recorded and preserved, the history is entirely unknown. On a recent visit to the splendid museum of Dupuytren, in Paris, which is well worth visiting, and well repays the time spent within its walls, I was very much pleased with the number of specimens of ankylosis I saw of the various articulations in the body. The causes, nature, and treatment of ankylosis in this articulation are very much the same as in the knee-joint, and a repetition of my remarks would be quite unnecessary here, and I would ask you to look back to my lecture on that subject.

STIFF ELBOW-JOINT.

In the fibrous variety of ankylosis, causing what is called *stiff elbow-joint*, there are two treatments at our disposal, occasionally modified, owing to the circumstances of the case—*viz.*, non-mechanical and mechanical.

1. Non-mechanical treatment implies a certain amount of manipulation applied with steady and determinate force so as to break up the adhesions which have occurred either internal or external to the articulation. The case to be a favourable one for success in this treatment must have an articulation free from any active osseous or articular derangement or inflammation, which may, however, have existed at some previous period, but for the present all inflammatory process must have subsided, and all sinuses about the joint perfectly healed before any forcible manipulatory measures are resorted to. When such rules are attended to, a good and serviceable joint may be very fairly anticipated. In others that are rashly attempted, and adhesions ruptured with excessive force, while inflammatory action is actually present, failure and disappointment cannot but be expected. As regards breaking up these adhesions under the influence of chloroform, it is remarkable in some cases how little inflammation is set up by forcibly extending or flexing a joint. In others, however, in a few hours, violent inflammation, with all the concomitant symptoms, are plainly seen. Much, however, I believe, depends on the management and after-treatment of the case, and you should order cold evaporating lotions to be applied locally. Bowels to be kept free and constantly open by saline purgative draughts, and to always have your patient fully under the influence of chloroform before you begin to extend or flex, as the case may be. If you want to extend, it is safer to fully flex in the first instance, as adhesions can be broken up by flexion as well as extension.

2. Mechanical treatment comprises all the mechanical screw appliances recommended from time to time for remedying this distortion; they are all, however, made on the same principle, for the arm is generally stiff in the flexed or bent position, and the instruments recommended are used for the purpose of gradually inducing extension. They consist simply of two padded metal plates joined at the elbow in the form of a hinge connected by a screw, which is so placed to move the plates to any angle re-

quired. Fig. 24 represents an instrument recommended by Bonnet for restoring motion by the *gradual plan*.

FIG. 24.

Appliance for Curing Stiff Elbow-joint.

It also shows very clearly the mechanism of the appliance; and this, or modifications of it, is what is generally found most useful. My objection to this plan is that it is far too slow and tedious, and tires out your patient long before the deformity is completely remedied; besides, where there are strong and firm adhesions, such an instrument would never rupture them without using very great force; and when they can be so easily broken down with the judicious force applied by the surgeon, and when the patient is fully under the influence of chloroform, and attended, when care is taken, with so little inflammation, I see no reason for discontinuing such a practice. I have broken up adhesions over and over again, and in none of my cases was there any more inflammation than might have been expected; but in nearly all the motion was perfectly, safely, and expeditiously restored. Occasionally a combination of the mechanical and non-mechanical treatment may be deemed advisable in some cases; in others, again, where there are tense strong superficial bands of integument, dividing such subcutaneously with a tenotome may be useful. In the cicatrization after severe burns, much contraction and adhesion are frequently present.

(To be continued.)

CASE OF DISEASE OF HIP-JOINT—EXCISION—RECOVERY WITH A USEFUL LIMB. (a)

By J. K. BARTON, M.D., F.R.C.S. Irel.,
Surgeon to the Adelaide Hospital, Dublin.

WILLIAM FINNY, a very delicate-looking boy, *æt.* 13, was admitted for the third time into the Adelaide Hospital on the 13th of June, 1874, suffering from disease of the right hip-joint in an advanced stage. His previous history was as follows: Five years ago, when eight years old, he received a hurt, when attempting a jump, in his right hip. Six months after the hurt he came into the hospital for the first time, suffering from severe pain in the right hip, and the other signs of disease of that joint in an early stage. Complete rest, a weight to the foot, and an issue behind the trochanter relieved the patient so much that the symptoms disappeared, and he was able to go out to the Convalescent Home in the following summer, where he remained a few weeks, and then returned home, free of pain, but still lame. For nearly two years he seems to have remained much in the same state; but in July, 1872, his mother again applied for his admission to the hospital, as a large abscess had formed at the back of the joint. This was poulticed, and allowed to open of itself, which it did in

(a) Read before the Surgical Society of Ireland, January 8. The discussion will be found at page 97.

about a fortnight after his second admission. A weight over a pulley was again attached to his foot, which gave him marked relief. In the following February he was so much better as to be able to go about on crutches. He then was sent to the Convalescent Hospital for a month, and after this he obtained admission to a similar institution at Sandymount, where he remained eleven months, during which period I occasionally saw him. His right leg was shorter than the other, but he had partial use of it, and could get about on his crutches very well. His general health was only indifferent; he was very thin, and looked badly nourished, although well fed. He was free from any pain in the joint, but the sinus still discharged daily a thin purulent matter. During the early part of the past summer he seems to have been obliged to use his leg much more than before, and this increased exertion was followed by the formation of another abscess, which was accompanied by very severe constitutional disturbance of a hectic type. When admitted for the third time, in June last, he was in such pain that his mother carried him on her back into the ward, this method of being lifted being the only one he could bear. When placed in bed and submitted to examination I found that the abscess was but small, in front of the joint, and did not seem to extend to any depth, it evidently could not be the cause of the pain or the constitutional disturbance. There was constant severe pain referred to the region of the joint, and the slightest pressure on the great trochanter greatly increased this. The poor boy lay on his back, his face shrunken, an expression of constant pain, his leg and thigh slightly flexed; pulse, 112; temperature, 101.2°.

The opinion I formed was that a fresh attack of osteitis had been set up by increased use of the limb, which the boy stated he had been obliged to make latterly. A 3lb. weight to the foot and opium internally gave some relief; but it became quickly evident that the boy's life was placed in peril by the continuance of the disease, and that unless relieved from the cause of irritation that he would sink. Encouraged by the success of the former case, in a still more unpromising subject, my colleagues agreed with me that excision should be performed, and accordingly, upon the 25th of June, I excised the upper extremity of the femur, the section of the bone being made immediately below the trochanter; the ligaments offered but slight resistance, the *teres* having totally disappeared, the head of the bone was much reduced, presenting the appearance of a truncated cone, the cartilage being totally destroyed; the acetabulum was found widened out, and deprived of its cartilage; but there was only one spot, about the size of a sixpence, which was carious, and to which, consequently, the gouge was applied. No vessel required ligature. The corners of the wound were closed with sutures, while the greater part remained fully open, the large cavity being filled with charpie soaked in carbolio oil.

The leg was laid on a long straight splint, but as soon as the boy was conveyed to bed this was removed and the weight substituted, a short inside splint being added to prevent any rotation. Very troublesome, although not severe hæmorrhage, came on the same evening, which compelled me to plug the wound with pledgets of lint soaked in *liq. ferri*. No vessel could be seen, but blood coozed up from the bottom of the deep cavity. This recurred two or three times during the first three days after the operation. As soon, however, as suppuration commenced, all tendency to hæmorrhage ceased, and the whole of the wound could be syringed out; so the large cavity was dressed from the bottom daily with charpie wetted either in carbolio or chloride of lime lotion. Opium had to be given to control pain and procure sleep for two or three weeks after the operation, but gradually this became unnecessary. The bowels caused considerable trouble, from the tendency to remain obstinately confined.

Gradually the deep cavity contracted, the upper end of the cut femur, covered with vigorous granulations, slowly became drawn up into the acetabulum, and the leg became at the same time more fixed and under the patient's control. The progress of the case was slow: it was not until

the latter end of September, three months from the time of the operation, that he was allowed up on crutches; since then his progress to health has been more rapid, and upon his leaving the hospital, about three weeks since, the following was his condition:—

As he lay on his back the two legs were seen to be perfectly parallel: the right measured 2½ inches less in length than the left; both seemed equally well nourished. When told to raise the right leg from the bed, he did so with ease, and as to lift the foot about fifteen inches off the bed; this was evidently accomplished by the rotation of the pelvis on the opposite femur. Upon examining the wound, a deep cicatrix marked its position, at the bottom of which a sinus remained open; a probe passed into this entered about an inch, but came to no bone. A few drops of pus were discharged daily from this. When told to get up, he did so readily, and stood erect, supporting himself upon the toes of the right foot. With a crutch he walked easily and rapidly, aiding himself by the toes of the right foot, which touched the ground. He had no pain, had a good appetite, and slept well.

He left the hospital a few days before Christmas day last, six months having then elapsed since the operation.

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

THE Society met on the evening of Friday, the 8th January, Mr. TUFNELL, the President, in the chair.

Dr. BARTON read a communication on

EXCISION FOR DISEASE OF HIP-JOINT,

which will be found at page 96.

The PRESIDENT said he thought such cases as that described by Mr. Barton would be prevented going to the extremity they had hitherto been allowed to go by the use of the water-cubation, which enabled the patient to be laid on his back and kept in a straight position.

Mr. BARTON had seen several instances in which the patient had been laid up and the limb so much improved that they were allowed to get up; but using the limb was invariably followed by a relapse.

Mr. McDOWELL: Did you think it was a case in which the discharge was running down the patient?

Mr. BARTON: Yes.

Mr. FLEMING said he had had an opportunity of seeing this case, and he never recollected having witnessed one in which the results reflected more credit on the operator, on the one hand, or were more calculated to make a favourable impression, with respect to the operation, on the other. There was very little shortening of the limb, and it had rather increased in length since the operation. The case was one of great practical interest, and the statement made that evening respecting its progress confirmed the view he took of the case when he had an opportunity of seeing it.

Dr. SWANZY read a paper on

A CASE OF RAPID AMAUROSIS,

which will be found at page 89.

In the succeeding discussion Dr. C. FITZGERALD, under whose care the patient had been, wished to make a correction on one point, namely, with respect to the paralysis the man exhibited when he got the seizure in the South Union, for it was an interesting point, and difficult to describe. The right side of the face was partly paralysed, there was ptosis of the left eyelid, and the tongue deviated to the left, and not to the right.

Dr. HENRY KENNEDY had seen a considerable number of cases like the present, but instead of occupying a year, as this had done, they ran their course in a few weeks. He should like to know if there was any effusion into the ventricles in this case. It struck him that the case was somewhat like those given by a late writer on the subject of syphilis affecting

the nervous system. He did not hear whether mercury was used in this case, but he had seen some benefit result from its administration. Generally speaking, he had seen these cases in connection with stromous disease.

Dr. SWANZY replied that there was no effusion into the ventricles, no fluid at the base of the brain or any part of the cranium. Anything that was there was firm lymph. No mercury was given, for he could not make any diagnosis or see any reason for giving mercury. There had been no syphilis. It occurred to him that there might be an explanation for the gangrene of the feet—that it might depend, perhaps, on the paralysis of the vaso-motor nerves arising at the base of the brain, if they do arise there. As it was not decided whether they do arise there, he did not wish to speak positively on the subject; but if they do, it is easy to understand that they would be paralysed, and would thus give rise to gangrene of the feet.

The Society then adjourned.

PATHOLOGICAL SOCIETY OF DUBLIN.

THE usual weekly meeting of this Society was held on Saturday, January 9th,

Dr. HENRY KENNEDY in the Chair.

INTRA-CRANIAL TUMOUR.

Dr. YEO exhibited for Dr. Gordon the brain of a female, *æt.* 20, who had been under Dr. Gordon's observation for five years, during which time she had suffered from epileptoid attacks, attributed to a slight injury of the head. She then became stupid, and the fits increased in number until they reached several in a day. The stupidity increased until it was almost impossible to obtain any information from her. She became perfectly blind, and remained several days in a semi-comatose state before her death, which took place on the 7th of January. The body was considerably emaciated, but the autopsy showed that the thoracic and abdominal viscera were healthy. In the anterior part of the cerebral hemisphere of the left side there was a tumour about the size of an orange immediately next the corpus striatum, but not implicating the optic thalamus. The external or peripheral part of the tumour was extremely dense, white, and non-vascular, the central portion grey, and very vascular. The microscopic examination showed that the different parts were composed of various forms of tumour, named by Virchow glioma, the peripheral part being simple sclerosis, the centre having undergone myxomatous degeneration. The specimen showed admirably the characteristics of a form of tumour which is not commonly met with.

STRANGULATION AND GANGRENE OF INTESTINE.

Dr. WM. MOORE showed a morbid specimen taken from the body of a woman, *æt.* 26, who was admitted into Sir P. Dun's Hospital on the 28th of November last. On the night of the 21st November she had eaten about a quart of cockles, and the following morning she was seized with violent abdominal pain and vomiting. Enemas were employed, but without avail. After admission into the hospital on the 28th the vomiting was checked, but the pain persisted, its main seat being referable to the inferior umbilical and hypogastric region. On the 3rd December the vomiting returned, the matter ejected being decidedly stercoraceous; this persisted till her death, on the 5th December. The post-mortem examination revealed a general adherence of the peritoneum, and in the hypogastric region a cavity, formed by the pelvis below, and behind, the agglutinated coils of intestines above, and the abdominal wall in front, contained a quantity of liquid feces, and in addition a loose gangrenous portion of intestine (the ileum), nine inches long, attached to the upper part of this cavity by a few shreds. About a foot and a half from the cæcum the ileum was found thickened, and two openings in it, through which a catheter could be passed upwards or downwards. A band from the mesentery had strangulated a coil of the ileum, which led on to ulceration and detachment. Dr. Moore considered that the mechanical weight of the impacted cockles had caused a coil of the ileum to drop into the pelvis, where it was strangled by this mesenteric band; and in connection with the question of the diagnosis of the seat of the obstruction from symptoms, he observed that the scantiness or suppression of urine so much

dwelt on by Barlow as pointing to obstruction of the small intestine did not hold in this case, as the patient passed urine in normal quantity up till the day of her death.

Dr. HAYDEN said that within the present session some examples of gangrene of the lung had been exhibited to the Society. He now proposed to bring under its notice another similar specimen. The patient was a woman, *æt.* 33, who was confined on the 29th October, and who imprudently went out three days afterwards. On the evening of that day she had a rigor, and then complained of pain in the chest, and had a cough. On the 18th November she was admitted into the *Mater Misericordie* Hospital, and on the following morning he saw her for the first time. She was remarkably pale, and had a puffed and pasty aspect. She also had a very distressing cough. The pulse was rapid, and she complained of very great pain in the chest. The heart acted tumultuously, but feebly; its sounds were normal. On the evening of the 19th there was congestion of the base of the right lung; the sputa were blood-stained. The specific gravity of the urine was 1.020. It contained no albumen. On the following day crepitation and percussion and dulness were distinct. The sputa were deeply tinged with blood, and in large quantity. On the 21st the skin was hot and dry. The left lung exhibited evidences of solidification. About this date, for the first time, she complained of pain in the left leg. There was œdema of the left foot, the sensibility was extreme, and she could not bear to be touched. On examining the groin he detected cord-like hardness, which would lead to the conclusion of lymphatic engagement; she also complained of pain in the region of the uterus. There was effusion into the left knee-joint. Under ordinary treatment she improved, but in the course of four or five days decided fœtor of the breath was discernible, and the sputa were of a gangrenous character. In this state she continued until the 24th of December, when she died, apparently worn out. For some days before her death he was not able to make a satisfactory examination of her chest, so strong was her objection to be disturbed. However, he succeeded in making an examination sufficient to afford evidence of the following condition: There was decided dulness of the lower half of the right side, with defective respiratory sound, in fact, it was almost *nil* in the early stages. There were coarse crepital râles, which ultimately became a guggle. There were no metallic phenomena. The autopsy showed that there was some effusion into the peritoneum. The left femoral artery, to the extent of two inches below Poupert's ligament, was of a pink red on the internal surface, but with this exception the line of membrane of the femoral vessels was normal in appearance, and there was no clot in either. He regretted to say that an examination of the uterus was not made. There was some effusion into both pleural cavities. The liver was found enormously enlarged, fatty in a high degree, and adherent to the diaphragm. He had examined a portion of the structure of the liver, and found it to be in a most advanced stage of fatty degeneration. The heart presented no remarkable feature, and was not fatty. The kidneys were fatty. The right lung was firmly attached to the diaphragm, and in the lower part of it he found a large gangrenous cavity containing a quantity of fœtid matter. The walls of this cavity, which were traversed by bands enclosing blood-vessels, presented a ragged appearance. The point of interest in the case lay in the connection of pneumonia with phlegmasia dolens. His conclusion was that there must have been a blood-clot detached from the uterine or adjacent veins, and impacted in a branch of the pulmonary artery, giving rise to infarction, inflammation, and gangrene of a limited district of pulmonary tissue. The history of the case led to this view; also the circumstance that the woman had led a healthy life, did not drink, and there was no evidence of antecedent illness. The surfaces of the right lung and pleura were remarkably thick. On laying open the pulmonary artery a plug was found in the tertiary division of its right branch, where it ran right forward to the abcess. The case was interesting in connection with one reported by his colleague, Dr. Nixon, a short time since.

Dr. T. E. LITTLE brought before the Society

A CASE OF DOUBLE FRACTURE OF THE SPINE WITH INJURY TO THE SPINAL CORD,

occurring in a man who had, while in a state of intoxication, fallen from a window which he had mistaken for the door of a room. When admitted to Sir Patrick Dun's Hospital

he displayed very few symptoms of the serious injury which caused death. He complained almost solely of pain and tenderness in the regions upon which he had fallen—the back of the neck, shoulders, and back of the head. About four days after he had entered hospital he developed certain symptoms which pointed to injury of the spinal cord—slight paralysis of the upper extremities, left arm and hand. As had been several times remarked by him (Dr. Little) as occurring in the early stages of injury to the spinal column, this patient's face and the upper part of his body were flushed to a remarkable degree. He had also a troublesome cough, and the diaphragm appeared to be the only vessel by means of which respiration was being carried on. He also complained of severe and frequent spasms in the thighs and calves of his legs. There was, however, no *anæsthesia*. He subsequently had an attack of diarrhœa; but Dr. Little could not connect it with injury to the spinal cord. The dyspnoea became much aggravated, the cough tickled him a great deal, and he was unable to expectorate. His pulse was 104; temperate 100°. His death appeared mainly to be due to the abnormal respiratory symptoms. The autopsy showed there were fractures between the third and fourth cervical vertebrae, and at the seventh, the injury to the upper being the more serious. The injuries to the cord were at the seats of fracture. The interest of the case was the progressive character of the symptoms and the slight amount of lesion to the spinal cord that was sufficient to cause the man's death.

The Society then adjourned.

WEDNESDAY, FEBRUARY 3, 1875.

BOARDING OUT AND INFANTICIDE.

THE National Committee for promoting the boarding-out of pauper children has just issued its third annual report, and we rejoice to see that its labours are being gradually crowned with success. The plan is being adopted in new districts, and everywhere favourable reports are made as to its operation. The Committee calls renewed attention to the immense evils attending the prevailing system of dealing with pauper children. Crowded together in large numbers, it is impossible they should receive that careful attention necessary to true physical, mental, and moral education. It cannot be too often recalled that last session it was authoritatively stated in Parliament that in St. Pancras Workhouse 89 children out of 407 had died during the previous year, being a mortality of 210 per 1,000. This may, as the Committee observe, be an exceptional state of things; but pauper and district schools are notoriously unhealthy, and everyone knows to

what an extent ophthalmia in particular prevails in them. Besides, "poor orphans, many of them the offspring of virtuous and industrious parents, snatched away by death, are too frequently exposed to the corrupting companionship of the degraded class of casual children, the offspring of thieves, tramps, and vicious women."

"Boarding-out not only brings more healthy influences to bear on children; it is the cheapest mode of solving a great problem which has yet been devised." So says the Report. Professor Fawcett and other economists complain that it tends to hold out inducements to the neglect of children by their parents, and there is no doubt that there is a very great amount of truth contained in that view of the case. Indeed, take away the responsibilities of rearing their own offspring from the poorer classes, and they would doubtless, as kings and queens do, launch forth into the production of posterity at a most alarming rate.

It must be remembered, and the excessive mortality of our large cities has just been spoken of by quite a host of learned men at the Sanitary Congress at Birmingham, that in the case of the poor, who usually marry as young as they can see a way to do so, many of the children die from privations of all kinds due to the distressed condition of their parents. Now, if it were very easy for such parents to hand over any of their children to pauper asylums where they could be boarded out, there would soon be an immense increase of children demanding admission to such asylums, as formerly to Foundling Hospitals.

The mortality of children in different countries in Europe is a very good index of the comfort of the poorer classes in each State. Thus, in Norway, where the condition of the peasantry is probably superior to that of all other European countries, out of 100 children born, 83 attain the age of 5; in England, 74; in Russia, 62; and in Italy, 61. Comparatively few children are, of course, wilfully killed or exposed by their own parents, but there can be no doubt that the great distress caused by a numerous family causes many mothers to neglect their children in a way which no less certainly causes death. All physicians must see this.

Infanticide, however, is by no means unknown in London, for, in one district alone—Central Middlesex—the number of cases increased from 84 in 1863 to 114 in 1865, where children were found exposed, many of them, however, supposed to be still-born children, which were left in the streets to avoid the expense of burial. Many bodies of infants are thrown into the river and the canals or other places, by persons who are unable to pay 7s. 6d. for their burial. Infanticide in London, it would seem, is chiefly confined to the class of domestic servants, and it is no use concealing the fact that female domestic servants are very much exposed to the temptations which result in their having illegitimate children. The mother of such children, in the present state of social life, is in the greatest difficulty, since she finds it very difficult in most instances to get a living, unless she goes into the work-house, whence, once entered, and her child brought into the world, she finds herself unable to make her exit, because she cannot leave the child behind her, and cannot obtain, in many cases, sufficient wages to pay for the honest nurture and care of her child.

Hence arise those cases of baby-farming, about which so much has been said in England, and above all in France, the country *par excellence* of nursing-out of infants. In London, the infants of those domestic servants who are unlucky enough to become pregnant, without securing the certain co-operation of the father of their child in its rearing and nurture, are compelled to hand over the infant to women, who must, of course, live by the trade of nursing. Such poor women receive a weekly pittance from the poor mother from her scanty wages, and attempt to rear the child by hand.

Every medical man knows how hard it is to rear an infant by hand, when the most sedulous care is taken of it; but how much more unlikely is this to be the case where the nurse is poverty-stricken, ignorant, and without affection for the poor infant? Hence, of course, in London, almost all of such nurse-children die.

In Paris the matter is now taken up by the municipality, and a supervision of the infants put out to nurse is obligatory. And with what results? Why, that the great majority of the children also die, when they leave the care and love of their mothers to be conveyed down in waggons to Nogent-le-Rotrou or some of the noted nursing villages adjoining Paris.

We observe in this week's *British Medical Journal* that the Parisian correspondent of our respected contemporary is, as is usual with the Press of this country, uttering a sorrowful lament as to the paucity of births occurring in France, and the stationary character of the French population. But, in the face of the immense mortality of the children of our manufacturing towns, such as Manchester, Liverpool, and Glasgow, we really cannot see anything to pity France for, because the fathers and mothers of that prudent nation do not care to bring so many infants into life only to be killed by ricketts, scarlatina, bronchitis, or starvation, as the inhabitants of our large cities evidently are so prone to do.

Nay, we very much doubt the advisability of those Parisian mothers who are so addicted to business or pleasure as to send away their newly-born infants by the "*Chemin de Paradis*" (as the carrier's carts are called, because the infants almost all die) having any children at all, until they learn that the first duty of a human being is to refrain from bringing into being creatures who are to be only neglected, ill-treated, and unfortunate.

The late Dr. Lankester used to say that a certain considerable proportion of all the women met with in the streets of London had committed infanticide. The former coroner, Mr. Wakley, used to think it the best policy to say as little as possible about such cases; but it must be confessed that human affairs do not go on well without open discussion. The immense infantile mortality of our towns is a disgrace to our intelligence as heads of the animal kingdom. That there should be myriads of the young of the lower animals destroyed in the struggle for existence, we can readily understand; but that society should see with complacency the terrible and ceaseless slaughter of children in Liverpool or Glasgow, &c., which is at least six times as great as in healthy country districts, is not to be tolerated.

Cynicism of this kind amounts to a denial of all morality; and we have no patience with the self-satisfied wealthy

follower of Darwinism, who looks upon the sufferings and early death of infants and young children as only a way of obtaining the "survival of the fittest." Such lucubrations are silly, immoral, and in the highest degree dangerous to the happiness of mankind. As if, forsooth, it would not be a thousand times more pleasant, and infinitely more simple, to obtain the amelioration of the *physique* of the race by proper attention to the selection of parents; and, above all, to the question of not having more offspring than can be made happy, and well-fed, and educated.

How little has hitherto been really done for the condition of the poorer classes in our large cities! They have, indeed, been preached to mildly as to their duties in attending church, or keeping out of police-courts; they have occasionally had some attention paid to the water-supply; but where, until lately, have the poorer class been taught anything about the impossibility of living in health without a proper supply of air, food, and cleanliness?

To make our fellow-citizens enjoy a healthy life, and prevent the enormous waste of infantile life, which invariably goes on in our large towns, ought to be the medical religion of the remaining quarter of this remarkable century. To live a long life, and to live all our lives, ought by this time to be perceived to be the practical teaching of all medical science; and no other consideration should allow these wholesome truths to be obscured from the view of the medical profession. We can see but one difficulty in the way of the medical faculty taking the lead in matters concerning the health of the community—and that is, that it has not as yet been thought to be part of the education of the medical world to learn anything of the science of wealth, called Political Economy. The ignorance of this important science among the general public is glaring enough. It leads to all kinds of serious revolutions and plans of Utopian character for obtaining wealth without work. It leads to Communism and the grim spectres that desolated the beautiful city of Paris but the other day. In the case of the medical world, ignorance of political economy leads to narrow views as to the powers of sanitary science, to crude theories of hygiene, leaving out some of the most important points, and, above all, to utter confusion with regard to all that relates to sex and the relations between numbers and food. Had the medical world, indeed, the good fortune to possess among its members only a few who were familiar with the science as expressed by the great masters, Adam Smith, Ricardo, Levior, the Mills, and lately by Cairns and Fawcett, it would not be long before there would be some notable progress made; and it would no longer be able to be said in the latter quarter of the 19th century that the poverty and misery of our large manufacturing cities is a reproach to us both as philanthropists and as men of science.

Poverty and early death are as much the consequence of ignorance of Nature's laws as the construction of an unseaworthy vessel or of an insecure railway bridge. Weak social theories about wealth lead to death and destruction quite as surely as want of knowledge of mechanics.

THE IRISH COLLEGE OF PHYSICIANS.

THE five "Dissentients" of the Irish College of Physicians have published a reply to the counter-statement promulgated by the Fellows in answer to their "Dissent." We find it quite impossible to print even a portion of this reply in our present issue, and we therefore refrain from expressing any opinion upon it until we are able to lay the salient points in it before our readers. The letter of Dr. Atthill which we publish to-day requires from us, however, a notice of the arguments which he uses. The theorem which is supported by those who desire the perpetuation of the ballot is, that inasmuch as the administrative function in the College is reposed in the whole body of Fellows, it would be highly inconvenient that that body should be unlimited in number, as it would be if the election by ballot were abolished. We argued *contra* that it was never intended that the whole body of Fellows should hold the executive duty, and if it were found that the body would become too large for smooth working, that difficulty might readily be solved by taking power to form a council such as administers the internal affairs of other corporations.

Dr. Atthill pleads in reply, that in 1692 the Fellowships were limited by Charter to fourteen; that by an Act of the reign of George III., the Fellowship having by a former Act been thrown open to all comers, was limited to University graduates, and in 1862 the restriction was abolished, and all Licentiates were declared eligible "under such limitations as the President and Fellows may deem fit."

It appears to us that the misinterpretation of this phrase by the Fellows has been the *fons et origo mali*, for while Dr. Atthill appears to imagine that it would justify the Fellows in imposing any conceivable disability that they chose, it is read by us, in common with the "dissentients," to authorise the President and Fellows to submit candidates to any test (by examination, or as to length of service, or as to good repute) which might be reasonably imposed for the good of the profession. Dr. Atthill would, we are certain, not consider the College to be entitled by this phrase to insist that all Fellowship candidates should stand six feet in their stockings, and it seems to us not much more reasonable that they should demand, as they did, that a candidate should achieve a popularity sufficient to secure four-fifths of the ballot vote.

Our contention is founded, however, not only on the ground that the requirements of the College from its Fellowship candidates are unreasonable, but on the abstract principle that the capacity to practise medicine is the *only* qualification which should be exacted from a claimant for a registrable medical diploma. We regard the Fellowship of the College of Physicians in this and in no other light, and we maintain that the good or bad opinion of any number of members of the profession should afford no cause either for the admission or rejection of a candidate, inasmuch as we look upon a registrable degree as the inherent right of every man who can display his competency to make use of it.

The "Dissentients," however, seem to have made no effort to meet the practical objection to the enlargement of the body of Fellows as long as that body exercises executive functions. They do not, we suppose, suggest that the Fellowship should be indefinitely extended (say to the number of 400), and should, nevertheless, continue to manage the internal affairs of the College, and yet they not only offer no alternative, but, individually, they have persistently resisted and succeeded in defeating a proposal for the formation of a Council.

In the petition to the Queen for this Charter, as at first drafted, a clause was contained which prayed Her Majesty to grant to the College powers "to constitute a Council consisting of the President, Vice-President, and nineteen Fellows . . . to regulate and manage the affairs of the College in all particulars that are not by Charter or Act of Parliament already directed to be done by the entire body." This clause was adopted by the College on the 20th of December, 1872, but was subsequently, on the motion of Sir Dominic Corrigan, modified by restricting its operation to the time when the Fellows should exceed one hundred. Nay, more! The clause was finally struck out of the petition on the motion of Dr. Lyons.

These two individual "Dissentients" have thus laid themselves open to the charge of having engaged in a resistance to the ballot without making any effort to render its abolition possible, and we think the course they have pursued calls for explanation, and until such explanation is offered, the Fellows are entitled to say that, however desirable the unlimited admission of Fellows may be in other respects, it is practically impossible without plunging the College affairs into a chaos of mal-administration.

There is one other point raised in the controversy to which we wish to refer to-day. In our issue of the 20th of January, referring to the statement of the College that they were merely asking a privilege of ballot granted to nearly all the medical corporations, we said that "on a careful perusal of the Ballot Committee's report we have been unsuccessful in finding a single case of a corporation in which the ballot was used under circumstances strictly analogous to those of the College of Physicians. We find therein instances of ballot in the election of officers of a College; of ballot as a secondary qualification after examination; and of the use of the ballot as an exclusive test in some societies; but we have found no precedent for the exclusion from, or admission of any person to, a legal medical or surgical qualification solely by the votes of those who already hold the degree."

As this statement has been challenged, we have again examined the Committee's report, and we have been still unable to find a case "strictly analogous," or a "precedent for the exclusion of any person solely by the votes of those who hold the degree."

There are only three licensing corporations besides the College of Physicians itself in which the ballot is enjoined in the Charter. This is, of itself, an important difference between these bodies and those in which the ballot is permitted by the bye-laws, because the Charter is irrevocable by any act of the corporation itself, while a bye-law may be at any time rescinded with or without the approval of the Secretary of State. There is much more granty, therefore, in the grant of such a power by Charter than by bye-law. The three bodies in which the ballot is enjoined by Charter are the Irish, English, and Scotch Colleges of Surgeons. In the Irish College the ballot is used for election of Council *not* of Fellows, and there is, therefore, no analogy. In the London College the admission of Fellows by ballot is restricted to those who were members on the 14th of Sept., 1843, and all others must submit to examination. Lastly, in the College of Surgeons of Edinburgh the ballot is only subsequent and subsidiary to the examination. We believe, therefore, that we are justified in saying that the instances in which the ballot is permitted, quoted by the Committee, are not strictly analogous to that of the Irish College of Physicians, where an elective power by ballot, without any other test, is sought to be secured by the Charter. But, in truth, this point is not of great importance. The "Dissentients" do not object to the ballot, on the ground that it has no precedent, but on the ground that it is unjust and inexpedient, and it does not make their case the less strong, because a certain number of corporations may have enjoyed the power of ballot some decades or centuries ago.

Notes on Current Topics.

Adulteration of Quinine.

The *Chemist and Druggist*, in its last issue, refers to remarks which recently appeared in our columns on this subject, and publishes a circumstantial statement from a well-known firm of chemical brokers in London, which corroborates forcibly the observations made in our pages. The firm quotes a statement from the *North China Herald*, published at the request of the Consulting-Surgeon to the Customs. The statement was to the effect that a package of 80 bottles of a white powder purporting to be sulphate of quinine was brought for examination to the Customs shed. The examiner immediately recognised the spurious character of the drug, and attempted to stop its delivery. On reference to the Acting Commissioner, it was ascertained that the Customs had no power of seizure. The value placed upon the "quinine" by the Chinese importer was 40 Mexican cents per ounce, or about one quarter of the cost at which genuine sulphate of quinine can be supplied wholesale by manufacturers. The bottle was made up to represent French manufacture. At the upper part of the label is a scroll bearing the words "Produits Chimiques." Immediately beneath this is the fac-simile of a medal. Beneath this, in a separate line, are the words "1 ounce," and beneath this again, in two lines, "Sulfate de Quinine, Paris." Messrs. Blagden and Angus, the firm who have addressed the *Chemist and Druggist* on the subject, says:—

"We recognised the article described as having been imported into Shanghai as identical in respect of labels, marks, &c., with a sample put into our hands a short time ago by a highly respectable house here.

"This sample had been sent to our friends by one of their Indian correspondents with an order for a large quantity. We submitted the sample to Messrs. Howards & Sons, and it was found on examination not to be sulphate of quinine at all.

"Of course our friends refused to execute the order, but there is little doubt that it was executed through another channel."

The Chemistry of Milk.

DR. CAMERON, the city analyst of Dublin, communicated last week to the Royal Dublin Society some interesting researches which he has made with reference to the chemistry of milk. He pointed out that the white colour and opacity of milk were not due, as was commonly stated, to the liquid being a fatty emulsion, but that they were owing to the fact that the fat globules in milk were invested with a caseous solid membrane which reflected light. By appropriate treatment all the fats of butter could be extracted from milk, and yet the residue would retain the characteristic appearance of that fluid. Butter-milk, which contained only 0.5 to 0.7 per cent. of fat, was yet a perfectly white liquid. In milk there were fat globules without investing membranes, but they were not numerous. The solids in cow's milk never sank below 12 per cent. in the case of town dairy cows, or 11.5 per cent. in the case of farm cows on poor pastures. In Dublin milk of average quality, and when pure, the solids averaged 13

per cent., and the fats 4.1 per cent. From ten analyses of Irish mares' milk, Dr. Cameron concluded the average composition to be—Water, 90.0; butter, 0.90; cheesy matter, 1.92; sugar, 6.78; mineral matter, 0.40—100. Sow's milk he found to be extraordinary rich, and to contain water, 81.72; butter, 5.66; cheesy matters, 7.06; sugar, 4.60; mineral matters, 0.96—100. It showed no cream on standing.

The Efficacy of the Contagious Diseases Acts.

ONE of the most forcible and convincing contributions to the abundant literature of the Contagious Diseases Act controversy has fallen from the pen of Professor Parkes, last week, and the accuracy of the statement and the closeness of the reasoning which the learned writer puts forward ought to go far to settle the question, even with the partisans who have hitherto declined to see or listen to evidence on the subject. In a letter addressed to the *British Medical Journal*, Professor Parkes says that he had asked Surgeon-Major Fox, of the Royal Engineers, to collate the number of admissions from primary syphilis and gonorrhœa during the years 1860 to 1874. The Contagious Diseases Act of 1864 was applied to Chatham in the middle of 1865; in 1866, '67, and '68, the Acts were only in partial operation. The results are as follows:—

From '60 to '65, *i.e.*, before the Acts, the admissions per 1,000 men were, on an average—for primary syphilis, 93.4; for gonorrhœa, 143.3.

From '66 to '68, when the Acts were in partial operation—for primary syphilis, 81.4; for gonorrhœa, 118.3.

From '68 to '74, under full operation of the Acts—for primary syphilis, 53.1; for gonorrhœa 78.0.

These figures, says Professor Parkes, speak for themselves. Both primary syphilis and gonorrhœa have been reduced nearly one-half. To what is this owing? To sanitary improvements? But these troops have been in the same barracks and under the same sanitary system since 1860. To lessened recruiting? The recruiting has been more active in the last period. In neither of these directions can a sufficient reason be found. It may, indeed, be possible that some of the very great lessening of admissions from syphilis which occurred in 1874 was owing to an order brought into force in the last half of the previous year, which imposed penalties on men with venereal diseases. This may have led to concealment of disease, and to an apparent and not a real diminution. But this cannot account for the lessening in the other years.

"Does anything remain," asks Professor Parkes, "except the operation of the Acts to account for the decline of these diseases?"

We hardly expect that (as the statistics of small-pox before and after the discovery of vaccination have failed to convince the vaccinophobiacs) the figures quoted by Professor Parkes will persuade the Contagious Diseases fanatics.

In connection with this subject we observe that the medical men of Liverpool have been forced to take public notice of one of the rash and entirely false statements which the opponents of the Contagious Diseases Acts have put forward. The following memorial is in course of signa-

ture, and has already received nearly two hundred attestations amongst the Liverpool practitioners:—

"To the Right Honourable R. A. Cross, Her Majesty's Secretary of State for the Home Department.

"It having been publicly stated that, of the medical practitioners in Liverpool, not more than twenty-six could be induced to sign a memorial in favour of the Contagious Diseases Acts, and that at the present time it would be impossible to find twelve medical men in Liverpool who are favourable to the said Acts, we, the undersigned medical practitioners of Liverpool, beg to express our approval of the Acts as at present in operation in seventeen garrison towns and ports in the United Kingdom, and to state that we are not in favour of a repeal of those Acts."

WE are sorry to notice in the columns of a contemporary the announcement that Dr. Rumsey, of Cheltenham, after suffering from severe cerebral symptoms, is now for some time incapacitated from work of any active professional kind. If any of its members have a special claim upon the profession, Dr. Rumsey is he. For years he has given his time and his best energies to their service, a sacrifice which is unhappily seldom appreciated by the mere money-making section of his brethren.

Irish Workhouse Supplies.

THE Irish Local Government Board have been obliged to write to the Kilrush guardians and express their opinion that more vigilance ought to be exercised as to the quality of the wine and other liquors supplied to the union. They based their remarks upon an analysis by Dr. Cameron, which stated that the port wine contained 19 per cent. of alcohol and 866.8 grains of sugar, nearly two ounces per pint, which clearly indicated that the wine was a very spurious article, and, in his opinion, a mixture of red wine, currant syrup, and spirits. The porter submitted contained 6.5 per cent. of alcohol, 4.63 per cent. of extractive matter, including 2.96 of sugar. It contained an over-due amount of water, and is a very poor stuff indeed. The tea yielded 34.2 per cent. of extract, and 6 per cent. of ash. Dr. Cameron considered it a very low-class article. The whisky was a very good article in point of quality. He found it, however, 13.5 under proof.

At the meeting of the Listowel Board a report was also read from Dr. Cameron. The tea, at 2s. 1d. per lb., was reported as being weak, and of the common or low-class quality. The coffee supplied was still worse, containing a mixture of more than half chicory. The whisky, which was supplied as 25 o.p., was found to be fresh, and 16 under proof. The Chairman, in referring to Dr. Cameron's report, said that it now appeared the inmates of the house were being supplied with articles very inferior to what the Board, up to this, supposed they were receiving. Mr. Hayes remarked that the Board might blame themselves to a great extent for this in accepting the lowest tender. Mr. Egan said that if a party tendered to supply the best black tea at one penny per lb. he considered the Board ought to accept it, and it would be for them to insist on the contractor performing the terms of his contract.

THE degree of M.D. Oxon. has been conferred upon George Bagot Ferguson, of Hertford College.

Definition of Adulteration.

We referred recently to the meeting of the Society of Public Analysts for the purpose of fixing upon a definition of what is meant by adulteration. They have completed their conference upon the matter, and have decided upon the following as the latter part of their definition. In the case of drugs, they shall be deemed to be adulterated—

1. If, when retailed for medicinal purposes under a name recognised in the *British Pharmacopœia*, any drug be not equal in strength and purity to the standard laid down in that work. 2. If, when sold under a name not recognised in the *British Pharmacopœia*, it differ materially from the standard laid down in approved works on materia medica, or from the standard under which it is sold. It was also resolved that the following should be deemed limits for the articles referred to under A. *Milk* shall contain not less than 9.0 per cent., by weight, of milk solids not fat, and not less than 2.5 per cent. butter-fat. *Skimmed Milk* shall contain not less than 9.0 per cent. milk-solids not fat. *Butter* shall contain not less than 80.0 per cent. of butter-fat. *Tea* shall not contain more than 8.0 per cent. of mineral matter, calculated on the tea dried at 100 deg. Cent., of which at least 3.0 per cent. shall be soluble in water, and the tea sold shall yield at least 30.0 per cent. of extract. *Cocoa* shall contain at least 20 per cent. of cocoa-butter. *Vinegar* shall contain not less than 3.0 per cent. of acetic acid.

The Quarter's Mortality in Dublin.

THE death-rate of the last quarter for Dublin is considerably higher than for the corresponding period of last year, and still further in advance of that of the previous year. Scarlatina caused 238 deaths, against 250 in the September quarter; and 151 in the fourth quarter of last year. Chest diseases have been very severely felt, in consequence of the terribly inclement weather. Bronchitis caused 338 deaths, those of this time last year, 287; and for the September quarter only 122.

The New Scriptures.

According to Tyndall, Huxley, Spencer, and Darwin.

In favour of the following clever *jeu d'esprit* we break our rule against the admission of such matter to our columns. It is taken from the columns of a Cincinnati paper, and, if read without irreverence, is a most amusing satire upon the materialist school:—

GENESIS—CHAPTER II.

1. Primarily the Unknowable moved upon cosmos and evolved protoplasm.
2. And protoplasm was inorganic and undifferentiated, containing all things in potential energy; and a spirit of evolution moved upon the fluid mass.
3. And the Unknowable said, Let atoms attract: and their contact begat light, heat, and electricity.
4. And the Unconditioned differentiated the atoms, each after its kind; and their combinations begat rock, air, and water.
5. And there went out a spirit of evolution from the Unconditioned, and working in protoplasm by accretion and absorption, produced the organic cell.
6. And cell, by nutrition, evolved primordial germ, and germ developed protogene, and protogene begat eozoon, and eozoon begat monad, and monad begat animalcule.
7. And animalcule begat ephemera, then began creeping things to multiply on the face of the earth;

8. And earthy atom in vegetable protoplasm begat the molecule, and thence came all grass and every herb in the earth.

9. And animalcula in the water evolved fins, tails, claws, and scales; and in the air, wings and beaks; and on the land they sprouted such organs as were necessary as played upon by the environment.

10. And by accretion and absorption came the radiata and mollusca, and mollusca begat articulata, and articulata begat vertebrata.

11. Now these are the generations of the higher vertebrata, in the cosmic period that the Unknowable evolved the bipedal mammalia.

12. And every man of the earth, while he was yet a monkey, and the horse, while he was a hipparion, and the hipparion, before he was an orodon.

13. Out of the ascidian came the amphibian and begat the pentadactyle, and the pentadactyle by inheritance and selection produced the hylobate, from which are the simiadae in all their tribes.

14. And out of the simiadae the lemur prevailed above his fellows and produced the platyrhine monkey.

15. And the platyrhine begat the catarrhine, and the catarrhine monkey begat the anthropoid ape, and the ape begat the longimanous ourang, and the ourang begat the chimpanzee, and the chimpanzee evolved the what-is-it.

16. And the what-is-it went into the land of Nod and took him a wife of the longimanous gibbons.

17. And in process of the cosmic period were born unto them and their children the antthropomorphic primordial types.

18. The homunculus, the prognathos, the troglodyte, the autochthon, the terragen—these are the generations of primeval man.

19. And primeval man was naked and not 'ashamed, but lived in quadrumanous innocence, and seemed mightily to harmonise with the environment.

20. And by inheritance and natural selection did he progress from the stable and homogeneous to the complex and heterogeneous; for the weakest died, and the strongest grew and multiplied.

21. And man grew a thumb, for that he had need of it, and developed capacities for prey.

22. For, behold, the swiftest men caught the most animals, and the swiftest animals got away from the most men; wherefore the slow animals were eaten, and the slow men starved to death.

23. And as types were differentiated, the weaker types continually disappeared.

24. And the earth was filled with violence; for man strove with man, and tribe with tribe, whereby they killed off the weak and foolish, and secured the survival of the fittest.

Unqualified Practice in an Irish County Infirmary.

As far back as last November we endeavoured to elicit from Dr. Browne, the Surgeon of the Galway Infirmary, an explanation of the fact that the duty of apothecary to the Infirmary has for the last eighteen months been discharged by a person who holds no qualification whatever, and that he is recognised and salaried as such by the Grand Jury. The circumstances of his appointment were stated by us to be the following. For very many years the appointment was held by Mr. Patrick Staunton, a licentiate apothecary, who died, leaving his nephew, who is now a practitioner in Galway, in possession of his business and in discharge of his official duties. This gentleman continued to act as apothecary to the Infirmary for a long period, and appeared from year to year in the list of officers of the institution. One morning, about a year and a half since, on going to the Infirmary, he found another person installed in office by order of Dr. Browne, the surgeon, without any notice whatever to him. From personal reasons Mr. Staunton refrained from complaint, and permitted the unqualified

practitioner to remain in possession. In pursuance of the course which we then stated our intention to adopt, we now ask the attention of the Apothecaries' Company to an open infringement of the law, and of their privileges; we request the notice of the Grand Jury and of the *sitting* Judge to the undoubted illegality of the payments made to the *soi-disant* apothecary; and we ask the profession to form their judgment of the conduct of Dr. Browne in establishing and maintaining an unqualified person in a position which ought to be held only by a medical man. We have reason to be satisfied that the case is accurately as we have stated it, and the reticence of Dr. Browne is accounted for by the fact that no satisfactory explanation of the circumstances is possible. It seems to us a most audacious proceeding that the surgeon of a county infirmary should assume to himself the right of displacing a properly qualified and competent medical man and inducting into his place an unlicensed person, and we are assured that—now that the matter has been publicly noticed—the Grand Jury will not continue to permit such an illegality.

Exclusion of Irish Medical Men from the Commission of the Peace.

It will be in the recollection of our readers that many months ago we called attention to the reply given by Sir M. H. Beach to a question put to him by Mr. Moore, the Member for Clonmel, in reference to the veto of the nomination of two magistrates exercised by the Lords Commissioners, who were then temporarily exercising the functions of the Lord Chancellor in Ireland. Lord Lismore had appointed to the Commission of the Peace a medical gentleman of repute in his county, and Sir M. H. Beach stated in the House of Commons that the appointment was cancelled because the Government does not consider a physician in practice to be a fit person to be entrusted with the Commission of the Peace. Having regard to the fact that for a long series of years practising physicians have been approved for the office of J.P., and have discharged their duties without the slightest suggestion of impropriety, and as everyone is aware that the Commission is every week granted to petty shopkeepers and persons infinitely inferior in social and educational status to the practising physician, we expressed ourselves as unable to comprehend the declaration of opinion of the Chief Secretary either as a statement of policy or as an authoritative insult to the medical profession. In the succeeding week's issue of the MEDICAL PRESS AND CIRCULAR we published a letter informing us that Sir Thomas McClure, the Vice-Lieutenant of the County Down, had refused to nominate Dr. Stuart for the Commission of the Peace on the ground that "the Lord's Commissioners would not sanction the appointment of any practising doctor, even if only consulting at his own house."

We believe that the attention of the Council of the Irish College of Surgeons was called to the matter, and it certainly appears to us to be deserving of their consideration; and yet they did not think it worthy of notice, and permitted this slight to be imposed upon the profession without remonstrance.

We are recalled to the subject now, having observed in the *Lancet* of last week the announcement that Dr. Pyle, of Sunderland, Dr. Underhill, of West Bromwich, and

Dr. Gisborne, of Derby, had been placed on the Commission of Peace, all of them being surgeons in actual practice. We would ask the attention of Mr. Moore, the Member for Clonmel, to this record, and we hope he will avail himself of an early occasion to interrogate the Chief Secretary for Ireland as to the reasons why the general practitioner of England should receive a distinction which is refused to the Irish medical profession—not, be it remembered, to an individual, but to the whole class.

This insult to the profession in Ireland, following not upon the exclusion of Her Majesty's surgeons and physicians in Ireland from the Viceregal entertainments, while their English brethren are regularly invited to Court in London, is, as we have before said, a premeditated official degradation which it behoves the profession to consider upon.

Abortionists and Diploma Vendors.

THE proprietors of the sham University of Philadelphia, we learn from the *Philadelphia Medical Times*, the chief income of which is derived from the sale of "bogus" diplomas—with the details of which traffic our readers are already acquainted—have been detected in the procuring of abortion, and one of "The Professors" sent to jail. Curiously enough, the abortion was produced at a house which has been the home of successive regular practitioners of excellent repute for very many years, until it passed into the hands of Mrs. Mixter and colleagues. A young woman was brought, some few days since, to this house, and an abortion produced by some one as yet unknown, from which she died a few days afterwards. The detectives in some way got wind of the affair, and obtained such information that they called upon Dr. Paine, the proprietor of the University, and asked if he knew anything about a body recently brought to his college. The learned professor stated that he did not; but, on the twin going to the institution, the janitor informed them that a Dr. Perpente, or Dr. Dubois, as he is variously named, had brought one into the college the day before. The dissecting-room was next visited, and the body was found, not as yet injected or in any way injured, but showing, it is said, very decided traces of criminal abortion. Dr. Perpente was arrested at his office about midnight the same evening. On going to Mrs. Mixter's house, it was found vacated, the bird having suddenly flown, taking seemingly only clothing and money, leaving everything else in the house just as last used. Of course Prof. Paine denies that Dr. Dubois had any connection with the institution; but, unfortunately, his name appears upon the official printed card.

THE operation of ovariectomy was performed on Saturday morning last at the City of Dublin Hospital, by Mr. Croly, Senior Surgeon, in the presence of many of the leading practitioners of Dublin, on a woman fifty years of age. The operation was completed rapidly, and the pedicle was secured by the clamp, the adhesions being altogether anterior, and the prognosis appears, as regards the operator, to be favourable. As the results of ovariectomy are a subject of much interest to Irish surgeons, we hope to report the condition of the patient in our next.

Winslow's Soothing Syrup.

We have more than once drawn attention to this and other dangerous narcotics, which are sold in large quantities to the general public, and pointed out that its sale should be under the restrictions of the Poisons Act. Surely there should be no hesitation in dealing with a matter which affects the health, and even the life of thousands of little innocents. Perhaps the proper authorities will heed the warning given in the last number of our American contemporary, *The Clinic*. It is not generally known that "Mrs. Winslow" is manufactured in America, thence imported to England, where it finds a ready market, in speaking of which before one of the American medical societies lately, Dr. Harlow denounced it as a poisonous mixture, that had not only killed its hundreds, but is spoiling the health of thousands of children. He stated that the amount sold yearly contains over fifteen million grains of morphia, which amount is administered to infants without professional advice with such dire results.

AN examination of candidates for twenty appointments as Surgeon in Her Majesty's Indian Medical Service will be held on the 15th February and following days.

THE Hunterian Oration will be delivered in the theatre of the Royal College of Surgeons of England by Mr. Frederick Le Gros Clark, F.R.S., President, on Saturday, the 13th of February, at 3 o'clock precisely.

ANOTHER meeting of the Hampstead Vestry was held on Thursday last, at which it was stated that two other sites had been offered to the Asylums Board for the erection of the proposed hospital for infectious diseases. Hope was expressed that the hospital would not be erected on the present site selected by the Asylums Board. The Works Committee reported that they had approved of a draft petition to Parliament against the establishment of the proposed fever hospital.

THE Registrar-General calls attention to the fact that during the last seven weeks there have been twenty-six fatal cases of small-pox in the metropolis, whereas only one occurred in the previous seven weeks. South London would seem to be the principal seat of the disease, as, with the exception of one in Whitechapel, all the rest occurred on the Surrey side. Three took place in the Stockwell Hospital, eleven of the inmates being unvaccinated.

IN London last week, 2,498 births and 1,569 deaths were registered. The births were 37 above, and the deaths 122 below the average numbers in corresponding week of the last ten years. The deaths had averaged more than 2,000 in the nine preceding weeks. The death-rate, which had been in the two preceding weeks 35 and 29 per 1,000 of the population, further declined last week to 24 per 1,000.

THE yield of the Hospital Sunday collection in Belfast has been, for 63 churches, only £607, a most discreditable

pittance considering the number and wealth of the factory owners, and the strong responsibility which lies upon them of taking care of their operatives. As a much smaller proportion of the population are Roman Catholics in Belfast than in Dublin, it was confidently expected that the contributions would have nearly reached those in Dublin, whereas they have hardly touched a fifth of the amount.

A CORRESPONDENT of the *Students' Journal* states that at the recent College of Surgeons primary examination 108 candidates presented themselves for examination, of whom no less than forty-four were plucked. Several of them were rejected for the fourth or fifth time, and two were sent back for the sixth time. One of these latter would, he says, have got through, in all probability, had it not been for the three B's. He had been prepared for the examination by a "grinder," and was well primed with artificial aids to memory. In the course of his examination he was shown the biceps muscle, which he at once recognised, but when asked what nerve supplied it, he was unable to recollect its name. After considering for a few moments, he said to the examiner, "I forget the name of the nerve, Sir, but I know very well; it's the nerve that supplies the three B's." (caraco-brachialis biceps and brachialis anticus). A friend of mine who attended the *vidu voce* examination last week, and watched the proceedings very closely, told me a few days ago that he was satisfied that not a single candidate was "plucked" who ought to have passed, whilst several were passed who, if they had had their deserts, would have been "plucked."

THE *British Medical Journal* has recorded this week a ludicrous error of its Dublin correspondent. The information of this gentleman appears to be a little unreliable, for he states that Dr. John Cronyn has resigned the Professorship of Midwifery in the Irish College of Surgeons to which he was appointed last week, and he proceeds to confer the chair, which he supposes to be vacant, upon one out of six candidates. The fact is, that Dr. Cronyn holds, and has not the least notion of resigning, his Professorship; but he has, in accordance with the obligation imposed by the Charter, resigned the Examinership in Midwifery, which our contemporary's correspondent might have ascertained if he had looked at the advertisement which appeared in our columns last week. None of the gentlemen who are named by the *British Medical Journal* are candidates, because the only two of them, Drs. Roe and Kirkpatrick, who being Fellows of the College, would be entitled to compete, are already Examiners in Midwifery. Dr. Croly, of Rathfarnham, who formerly held a seat on the Court, and Dr. Peter Shannon, of Dublin, are candidates.

Dr. Croly, of the City of Dublin Hospital, son of the gentleman whom we have named, is almost certain to be chosen to the seat on the Council vacated by Mr. Adams.

Literature.

MANUAL OF PUBLIC HEALTH FOR IRELAND. (a)

WITHIN recent years two events of national importance contributed to fix general attention upon a subject

(a) "Manual of Public Health for Ireland." By Thomas W. Grimshaw, M.A., M.D.; J. Emerson Reynolds, F.C.S., &c.; Robert O'B. Furlong, M.A., Barrister-at-Law; and John W. Moore, M.D., M.Ch., &c. Dublin: Fannin and Co. London: Longmans. 1875. Pp. 336.

directly bearing upon the public health; the first was the lamented death of the Prince Consort from typhoid fever, contracted, it is believed, in consequence of defective sewage at Windsor Castle; the second was the narrow escape from a similar fate of the Prince of Wales, the disease in his case being also traceable to defective sanitary arrangements in connection with sewage. The shock occasioned by the first event, and the intense anxiety awakened by the protracted and perilous struggle for life of the Prince of Wales turned the current of public attention in the direction of one branch of sanitary science, namely, the origin and prevention of zymotic diseases. As is usual in cases where the public interest is strongly diverted into a particular channel, the attention thus given to preventable disease extended to all the kindred topics connected with public hygiene. Society was interested, minds professionally trained devoted their energies to the subject, the public health and the questions involved in its consideration became a topic of special study, and every well-informed medical man was expected to grasp the general principles of a comparatively new but most important branch of professional knowledge. No stronger proof can be afforded of the importance that the whole question within a brief period had assumed than the declaration in favour of sanitary reform which was made by Lord Derby in a speech delivered at Bootle in April, 1872. The subject of State Medicine was by that speech presented to the public mind as one of the questions of the day. Opinion within and beyond the ranks of the profession was ripe for legislative direction, and legislation soon followed.

There was probably no portion of the United Kingdom which stood in greater need than did Ireland of intelligent legislation on questions of public health. There was certainly no portion of the United Kingdom which presented a machinery more complete and ready to hand for undertaking this important duty. The sanitary authority of the executive was to a great extent exercised or controlled through a Local Government Board, which, under its earlier title of the Poor-law Commission, had with consummate ability and judgment administered the laws for the relief of the poor, and had not only administered, but had organised and guided, a system of medical relief unsurpassed in its efficiency in any country in the world. By this central authority the country had been mapped out into unions and subdivided into dispensary districts, and from the earliest moment the highest administrative ability had marked the proceedings of that Poor-law Commission to which we shall henceforth refer as the Local Government Board. A singular earnestness of purpose characterised its procedure: by its strong central authority it supported the medical officers in the proper performance of their duties; with stern determination it repressed the often wretched parsimony of local boards of guardians, gradually elevating their views as to the sacredness of the trust reposed in them, and, as it were, educating them into a more enlightened exercise of their functions. Controlling at the same time the dispensary committees and the relieving officers, by very gradual steps it perfected the local machinery to such an extent that at any moment the execution of new and valuable functions could be entrusted to the existing organisation. Thus, when an act for the registration of births and deaths was extended to Ireland the existing machinery was so perfect that the measure passed into noiseless operation at a very moderate public cost.

"The Public Health (Ireland) Act, 1874," is the latest and most important measure which has been entrusted by the Legislature to the Local Government Board. It is also a measure in the successful working of which all classes of the community are interested. It appears to us that, complete though the existing machinery may be for carrying out its provisions, there are some other conditions necessary for its success—first, an enlightened and liberal spirit on the part of local boards of guardians,

and with regard to this point we need only remark that the public (who are most interested) and the profession will have to trust to the "sealed orders" of the Local Government Board. In our last issue we expressed our gratitude at the decided position taken up by them on this vital question of the adequacy of the remuneration to be given to the officers charged with the often disagreeable duties imposed upon them by the Act. In the second place we regard, as an essential condition for the smooth and efficient working of the Act, some degree of education on the part of the poorer class, who, while they will profit so much by sanitary arrangements, will be apt at first to regard interference, of medical officers especially, with suspicion and jealousy. Unhappily, in the case of the occupant of a cabin, the manure-heap and the domestic pig contribute to pay the rent. For some considerable time great forbearance will be necessary; time and patience will be required to educate the poorer class into the recognition of the fact that the interference of the sanitary officer is for their benefit and the public advantage when he insists upon the observance of the plainest rules of hygiene. We venture to think that something might be attempted in this direction by boards of guardians, through their relieving officers, through the diffusion of some elementary information on the subject of public health amongst the poor. There can be no doubt that much might be done in the course of a very few years, through the national schools for instance, by the distribution of a short catechi hehal uos tcom-f public-ised within the limits of a wall-tablet and hung up in every national school. That something of the kind can be done is evident from the fact that we have before us at this moment a most admirable code of rules entitled "Personal Precautions against Fever," which contains in a very small space the clearest possible precepts of unquestionable truth and value upon such topics as fresh air, pure water, wholesome food, clothing, personal cleanliness, and temperance, as prophylactics against disease. We do not know from what source the paper emanates, but it is so terse, so clear, and so valuable, that we can only say it deserves adoption by the Local Government Board, and its study by the rising generation would form an excellent introduction to sanitary science. We have also a recollection of having somewhere seen a collection of sanitary rhymes, inculcating in that plain verse which appears to leave so deep a mark upon the young mind, a knowledge of the first principles of physiology. Something of this kind is required to enlighten the dense popular ignorance, and to prepare it for an intelligent co-operation with the local sanitary authorities throughout the country.

Last in order, although first in importance, of the conditions necessary for the successful application of the Act—a condition to which we particularly direct the attention of our readers—is that there should be a competent knowledge on the part of the dispensary medical officers of subjects connected with public health, the duties they have to perform, and the technical knowledge, as well as the principles, which should guide them in the execution of their sanitary work; and this point leads us to the consideration of the valuable manual before us. The "Manual of Public Health for Ireland," as the title-page informs us, is the joint production of two most accomplished physicians, probably the highest authorities in Ireland upon the subjects with which they deal—Dr. Grimshaw and Dr. J. W. Moore; of a chemist of the first rank, Dr. J. Emerson Reynolds; and of Mr. Robert Furlong, barrister-at-law. Let us at once discharge the grateful task of congratulating the joint authors upon the result of their labours. The work before us leaves nothing to be desired. It opens with the Act itself, it gives the orders of the Local Government Board on the subject of the Act, the sanitary duties of authorities and officers, and a valuable index to all the Sanitary Acts bearing upon the subject. Then follow some most able chapters upon vital statistics, the conditions necessary to

public health, preventable disease, etiology of disease, food, water-supply, examination of water, house construction, drainage, sewerage, air and ventilation, hospital accommodation, disinfection, climate and meteorology, and the appendices in addition contain valuable tables for reference. Considering the great number of subjects comprised within the curriculum of the modern student of medicine, it would, we hold, be absurd to expect from every practitioner the technical knowledge so lucidly conveyed in the manual before us. It will, however, be very difficult for any sanitary medical officer to fulfil his duties under the Public Health Act without a greater acquaintance with subjects within the scope of State Medicine than is usually possessed by students who have just passed their qualifying examination. By all who are anxious to supply a deficiency which was inherent in the system under which they studied this volume will be welcomed as a perfect vade-mecum of sanitary law. We have no doubt that it is by this time in the hands of every sanitary authority, and that all will concur with us in regarding this manual as a most valuable addition to medical literature. The book deserves attentive study in every way, and we strongly recommend our younger professional brethren to observe not only the matter but the language in which the authors have conveyed their thoughts, and we may add that the form in which the book is issued, the paper, and letterpress, reflect great credit on the publishers.

Correspondence.

THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Believing that any editorial articles which appear in the *MEDICAL PRESS* on the subject of the “Irish College of Physicians” are dictated in a spirit of fairness, and with the intention of advocating what in your opinion is best calculated to promote the true interests of the profession, I take the liberty of addressing you, even though some of my remarks may appear to be a criticism on yourself.

After arguing against the use of the ballot in the election of Fellows, you proceed to say that it may be urged “that the Fellowship of the Irish College of Physicians is more in the nature of a seat on its Administrative Council than a high medical qualification;” and then you add, “We don't think that it was originally contemplated in the Irish College of Physicians that this should be so, and so long as the difficulty can be readily met by the appointment of a Council, we do not think that the body of Fellows ought to be restricted in order that the administrative efficacy pertaining to a small number should be maintained.”

These quotations involve three distinct and widely different questions worthy of consideration, namely:—

1st. Is the Fellowship of the Irish College of Physicians, as at present constituted, equivalent to a seat on the Administrative Council of the sister Colleges?

2nd. Was it originally intended that this should be so?

3rd. Is it advisable to meet “the present difficulty” by appointing a Council as suggested by yourself?

As to the first, it will, I think, be generally admitted that, as at present constituted, the Fellowship is equivalent to a seat on a Council, for all the Fellows, resident or non-resident, are summoned to every meeting of the College, and with them resides the decision of all questions brought before the College.

As to the second question, I believe I can show that it was originally intended that “this” should be so. By the Charter of 1692 the Fellowships were limited to fourteen; by the Act 1 Geo. III. they were made unlimited; but by another Act, 40 Geo. III., they were again virtually limited, being by it restricted to Graduates of the Universities of Oxford, Cambridge, or Dublin, and a very stringent limitation this proved. This Act was repealed at the request of the

College in the year 1862, the Act then obtained empowering the College to elect to the Fellowship “under such limitations as to them may seem fit,” such of its Licentiates “as may appear to the President and Fellows to merit such distinction.” Observe even in this Act, Licentiates are to be admitted only “under such limitations” as the President and Fellows may deem fit. I think, then, that no matter how this Act may be interpreted, it was originally intended that the Fellowships of the Irish College of Physicians should be limited, and be of the nature of a seat on a Council.

Before entering on the third question I would point out that in all the medical corporations, and in all the scientific societies of which I have any knowledge, the government is either vested in a Council, or the Fellowship, or its equivalent, by whatever name termed, is limited.

It is urged by the few dissentients who oppose any change in the governing body of the Irish College of Physicians that its Fellowships should be virtually unlimited, and that there should not be a Council. If their views be carried out to the full extent the influx of Fellows would be so great that its administrative power would be seriously impaired, for it would be impossible for a body consisting of two or three hundred Fellows to discharge its functions efficiently without the intervention of a Council. One of the greatest objections to an unlimited enlargement of the College as at present constituted is this—that it would cease to be a deliberative body, that its meetings would be made use of for the display of carefully prepared oratory. This tendency is already plainly manifested by the fact that reports of speeches delivered in the Irish College of Physicians are, from time to time, furnished to the daily papers, while it is gravely proposed to have newspaper reporters present at its meetings. Speeches nearly an hour long may be both amusing and instructive; probably they may be neither one nor the other: but certainly their delivery consumes much valuable time, and considering how precious time is to those of our profession who have risen to eminence, it is not to be wondered at that many are deterred from attending the meetings of the College; and it is impossible to over-estimate the serious injury their absence inflicts, not alone on the College, but to the profession at large.

With respect to the third question, I entirely agree with you. I unhesitatingly advocate the extension of the Fellowship and the institution of an elective Council, and I have done so always. Two years ago a resolution was moved in the College to the effect, that it was desirable to obtain powers to institute a Council, and more recently, when the Charter was being applied for, it was again proposed that a clause enabling the College to elect a Council should be inserted. On both occasions the supporters of the motion were out-voted, the opposition being led by the very Fellows who, to use your own words, “now object to the narrowness of the College.” Nay, more, the insertion of a permissive clause giving the College power, if it thought right to exercise it, of electing an Executive Council whenever the number of Fellows reached 100 was, though recommended by a Committee of the Fellows, successfully resisted by these gentlemen, the rejection of the clause being moved by Dr. Lyons. I hold that the Fellowship should be unlimited, but that there should be in that case a Council, and that if a Council be not conceded, that it becomes absolutely necessary to limit the Fellowship.

I am well aware that there are difficulties in the way of carrying out the course I advocate, but they are such as can easily be overcome. I am equally aware that objections exist to the mode of governing a medical corporation by means of a Council; but what mode of government, political or professional, is not open to objection from some quarter? and the objections which can be urged against the formation of an elective Council are of infinitely less weight than those arguments which can be brought forward in its favour. The mere fact that a Council exists in all the other medical corporations in which the number of Fellows is unlimited is a proof that it is the plan found best adapted to ensure the well-being of these corporations, and I trust the Fellows of the Irish College of Physicians will ere long join in demanding what cannot be refused—a constitution similar to that of the sister Colleges.

I am, &c.,

LOMBE ATTHILL.

Jan. 20th, 1875.

Medical News.

Royal College of Physicians of London.—William Guyer Hunter, M.D. Aberd., India, was elected as a Fellow of the College on January 28th.

On the same date the following were admitted Members :—

Francis John Corbould, M.D. Aberd., Reigate.
George Frederick Elliott, M.D. Dublin, Hull.
William Richard Gowers, M.D. Lond., 50 Queen Anne Street, W.
Edward Mackey, M.D. Lond., Birmingham.
William Harris Stretton, M.D. St. And., St. Bartholomew's Hospital.
Clement Duke, M.B. Lond., Rugby.
Sidney Coupland, M.D. Lond., 33 Elisham Road, W.
Benjamin Hunt, M.D. St. And., Edgbaston, Birmingham.
Arthur Evershed, 8 Belle Vue, N.

Admitted Licentiate :

Roger Edwards, University College Hospital, W.C.

Royal College of Surgeons of England.—The following having passed the required examinations for the diploma, were duly admitted Members of the College at meetings of the Court of Examiners on Jan. 25th, 26th, and 27th :—

Adkins, Edward James, Canonbury.
Balshaw, Edward Pass, Bayswater.
Barron, Thomas Walter, Sunderland.
Basham, William Richard, Westminster Hospital.
Black, James, Highgate Road.
Boddy, Evan Marlett, L.S.A., Camberwell Road.
Brodrigg, Francis Benjamin, L.S.A., Upper Clapton.
Buckland, A. G., L.S.A., Auckland, New Zealand.
Chapman, Paul Morgan, Camden Park Road.
Champneys, Francis Henry, Litchfield, Staffordshire.
Clutton, Henry Hugh, Westminster.
Collenette, Frank de B., L.S.A., Guernsey.
Cooper, Ernest Frederic, Canonbury.
Cumming, Hugh Gordon, Exeter.
Dent, Clinton, Thomas, Chesham Street.
Dearden, J. A., L.R.C.P. Edin., Douglas, Isle of Man.
Dixon, James Deighton, Gateshead-on-Tyne.
Duke, Herbert, Clapham Road.
Edmunds, Walter, M.B. Cantab., Hampstead.
Edwards, Roger, L.R.C.P., Dolgelly, North Wales.
Friend, Frederick Worrall, Bayswater.
Footner, John Bulkley, Romey, Hants.
Gonsalves, Manoel Martino, L.S.A., Cambridge Terrace, Hyde Park.
Haden, Arthur Chas., Sloane Street, Chelsea.
Hales, Robert Turner, Holt, Norfolk.
Haggood, Henry, Eastbourne, Sussex.
Hart, George Henry, Birmingham.
Harvey, William Yeo, Rutland Street, N.W.
Hastings, George, Brixton.
Hawkins, Alexander F., Blackrock, Dublin.
Hughes, William Lewis, L.S.A., Carmarthen.
Hutton, Edwin Rutherford, Lever Street, St. Luke's.
Jackson, Ernest Carr, Harley Street.
Jones, Valentine L. W., Carmarthen.
Jones, William M., Blaenavon, Monmouthshire.
Kains, Robert, M. B. Toronto, Palace Road.
Lee, Edwin, Leeds.
Lewis, Ivor Ajax, L.R.C.P., Llantrissant, South Wales.
Lovett, Henry Albert, Norwich.
Marks, Charles Ferdinand, Dublin.
Morris, Walter Cameron, Barbadoes, West Indies.
Newham, Francis, L.R.C.P. Edin., Oldham.
Newton, Edward Shackfield, Canonbury Park.
Owen, Herbert Isambard, Gloucester Gardens.
Parkes, Alfred, West Bromwich.
Paul, Ernest Watson, L.K.Q.C.P.I., Brixton.
Peck, Awdry, Bath.
Pink, Thomas, L.S.A., Greenwich.
Richardson, William B., Leeds.
Ross, Geo. Hamilton, L.R.C.P., Hart Street.
Roy, John James, Hammersmith.
Rudd, Leonard, Kempsey, Worcestershire.
Sall, Ernest W. H., Dolphin Holme, Lancashire.
Sampson, Henry Moore, Yeovil, Somerset.
Sargent, Arthur Francis, Belsize Park, Hampstead.

Smalley, Thomas, Pickering, Yorks.
Smalley, Herbert, Grays, Essex.
Smith, Sydney Lloyd, L.R.C.P. Edin., Brixton Road.
Spooner, Frederick Henry, Plymouth, Devon.
Strandling, William Arthur, Sloane Street, Chelsea.
Streeten, Friend Edward, Ealing, Middlesex.
Vaillant, Marie Edouard, George Street, Portman Square.
Wallis, Kenneth Serjeant, Cambridge.
Webb, Charles Lewis, L.S.A., Bentley, Hants.
Wharry, Robert, Charlton, Kent.
Williamson, Francis, Durham Place, Chelsea.

The following passed the primary examination in Anatomy and Physiology on the 21st ult. :—

G. A. Boodle, F. A. Hallsworth, G. R. Howat, H. M. Floyer, H. F. Chapman, J. W. Langdon, and H. L. Walcott, St. Bartholomew's Hospital; E. J. D. Boyard, J. C. Wilkinson, and J. S. Clowes, Guy's Hospital; R. Owen, Charing Cross Hospital; G. H. Hornsby, and H. G. Lowe, Birmingham; G. P. Best, and J. Biale, St. George's Hospital; J. Weller, London Hospital; W. P. Blackley, St. Thomas's Hospital; M. H. S. Allen, St. Mary's Hospital; H. S. Atkinson, King's College; I. L. Alleyne, University College.

Death of Dr. Jameson of Dublin.

WE regret to announce the death, on Monday last, of Dr. Jameson, formerly Surgeon to Mercer's Hospital, ex-President, and for many years a Councillor of the Royal College of Surgeons in Ireland. Dr. Jameson has been for a considerable time a sufferer from calculus, which was twice subjected to lithotomy, and to which he eventually succumbed.

NOTICES TO CORRESPONDENTS.

DR. CHARLES MAURIAC, Hôpital du Midi, Paris.—There is at this moment a grave debate going on in England and America about the result of Acts of Parliament which were framed to resemble the Bureau des Mœurs of Paris. We want much information on this subject here, and should feel deeply indebted to M. Mauriac if he would say whether there is much venereal contagion in Paris, and whether the Bureau des Mœurs succeeds in much lessening prostitution.

DR. DE SMET, Brussels.—Dr. Thiry, in one of his lectures, states that there is plenty of venereal disease in Brussels. Is this the case in your experience, and does the civil population of Brussels suffer much from syphilis and from gonorrhœa?

G. A. CARLETON, Boston, U.S.—Thanks for the *Laboratory*. We intend quoting from it shortly. Should like to hear your own experience of ophthalmology and skin diseases in Boston. How does heifer vaccination progress? How many female doctors are there in America now, and do they attract the confidence of their patients? Dr. Richelot, of Paris, has been writing a tirade against the Faculté de Médecine of Paris for admitting women to its medical degree, and has had the want of chivalry and bad taste to speak of Mrs. Garrett-Anderson and Mrs. Putnam Jacobs by name, and disparage the theses they composed. We don't know anything of Dr. Richelot except this piece of literature against women. The conduct of Mr. George Critchett and his honourable coadjutors is at once more manly and noble. They say, "It is not for us to prevent all women from studying medicine: let the public judge them as it has judged us by our merits—"caveat emptor." And this, doubtless, the just view of the case. We wash our hands of responsibility for the fate of all women. It is hard enough to try to secure the happiness of those we have to work for ourselves; we dare not legislate for the whole of the sex.

DR. H. R.—We have not deemed the subject of sufficient interest to refer to in our column.

Mrs. CARSTEN HOLTHOUSE.—Your communication will appear in our next.

DR. W. H. G.—Too late.

A STUDENT is referred to the *Students' Journal*, an excellent little fortnightly medium, containing many hints and notes which will be of service to him. We cannot answer the questions asked in these columns; probably our contemporary will give the information he seeks.

COMMUNICATIONS, Enclosures, &c., have been received from—Dr. Clinton Wagner, New York. Dr. Farr, London. Dr. Black, Cockburnspath. Mr. Thompson, London. Prof. Lombard, New York. Dr. Martin, Portlaw. Dr. Balthazar Foster, Birmingham. Dr. Lyons, Dublin. Dr. L. S. Forbes Winslow, London. Dr. Clare, Leeds. Dr. Byles, London. Dr. Hadden, Horncastle. Mr. Hy. Startin, Oxford. The President of the Medical Microscopical Society. Dr. Hilliard, Holloway. Mr. Oliver, Penge. Mr. Kemp, London. Mr. A. Crisp, Markham. Dr. Pritchett, Huddersfield. Mr. Day, Birmingham. Mr. Griffin, London. Mr. Blackett, Society for Relief of Widows of Medical Men. Dr. Handzel Griffiths, Dublin. Mr. H. Eschwaga, London. Mr. Kirkley, Sheffield. Mr. R. Savill, Nafferton. Mr. Austin, Liverpool Medical Society. Dr. Smith, Dublin. Dr. Tilton, Stonehouse. Dr. Hy. Day, Stafford. Mr. J. B. Edge, Manchester. Dr. Lane, Sudbrook Park. Dr. Hy. Harris, Redruth. Mr. J. Verdon, London. Dr. Lane, Douglas. Dr. Merrick, Letterkenny. Dr. Purdon, Belfast. The Registrar, Royal College of Physicians of London. Our Indian Correspondent, The Registrar-General. Dr. Harrison, Edinburgh. Dr. Williams, Manchester.

VACANCIES.

Royal Hospital for Diseases of the Chest, City Road. Physician. Honorary. Applications, with Testimonials, to be forwarded to the Secretary. (See Advt.)
 North Wales Counties Lunatic Asylum. Assistant Medical Officer. Salary, £100, with board and furnished apartments. Testimonials to the Clerk to the Visitors, Denbigh.
 Donegal District Lunatic Asylum. Consulting and Visiting Physician. Salary, £100 per annum. Applications, enclosing testimonials, to Dr. Merrick, at the Asylum. (See Advt.)
 Seamen's Hospital, Greenwich. House Physician. Salary, £120, with furnished rooms, &c. Applications to the Secretary.
 Fulham Union. Medical Officer for No. 5 District. Salary, £50, with the usual fees extra. Applicants must address the Clerk of the Union, Hammersmith, S.W.

APPOINTMENTS.

BEACH, FLETCHER, M.B., Medical Superintendent of the Clapton Asylum for Idiots.
 BRANWELL, B., M.R.C.S., Consulting Surgeon to the Brighton Dispensary.
 BRUNTON, T. L., M.D., M.R.C.P.L., F.R.S., an Assistant Physician to St. Bartholomew's Hospital.
 CARRE, Dr. F., Medical Officer, &c., for the Letterkenny Dispensary District of the Letterkenny Union, co. Donegal.
 COXWELL, J. E. G., L.K.Q.C.F.I., M.R.C.S.E., a Medical Officer to the Worthing Infirmary.
 DRURY, Dr. R., Resident Surgeon to the General Dispensary, Birmingham.
 ELLERTON, J. F. H., M.R.C.S.E., an Assistant Resident Medical Officer to the General Infirmary, Leeds.
 FLEMING, W. J., M.B., L.F.P. & S. Glas., Assistant to the Professor of Physiology in the University of Glasgow.
 GARTLAN, J., M.D., Superintendent Medical Officer of Health for the Dundalk Rural Sanitary District.
 JULER, H. E., M.R.C.S., Resident Registrar to St. Mary's Hospital, London.
 LAMB, W. H., L.R.C.P.L., M.R.C.S.E., House Surgeon to the Public Hospital and Dispensary.
 LEVINGE, E. G., A.B., M.B., L.R.C.S.I., Junior Assistant Medical Officer of the Hants County Lunatic Asylum, Knowle Fareham.
 LIVESY, Mr. E., Assistant House Surgeon to the General Infirmary, Derby.
 MAHON, C. J., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer, &c., for the Easkey Dispensary District, Upper Division, of the Droineur West Union.
 MEIGHAN, T. S., M.D., a Surgeon to the Glasgow Eye Infirmary.
 MUNRO, ENEAS, M.D., C.M., F.F.P. & S. Glas., Assistant Physician to the Hospital for Women, Soho Square, London.
 MUSGRAVE, S., L.R.C.P.Ed., Superintendent Medical Officer of Health for the Lisburn Rural Sanitary District.
 OLDHAM, C. J., F.R.C.S., Surgeon to the Brighton Dispensary.
 O'MEARA, F. A., L.R.C.P.Ed., Medical Officer of Health for the Southern Sub-district of the Axminster Rural Sanitary District.
 REEVES, H. A., M.R.C.S.E., P.R.C.S.Ed., Surgeon to the Hospital for Women, Soho Square, London.
 ROOSEY, Dr. J., Medical Officer, &c., and a Sanitary Officer for the Shercock Dispensary District of the Bailieborough Union, co. Cavan.
 SMITH, J. G., L.K.C.S.Ed., L.M., Medical Officer for the Parish of Reay, Caithness-shire.
 WHITE, B. S., M.R.C.S.E., L.M., Medical Officer for the No 9 District of the Brentford Union.
 WOLLASTON, R. G., L.R.C.P.Ed., M.R.C.S.E., Medical Officer for the Lyme Regis District of the Axminster Union, Devon.

Marriages.

LAKING-MANSELL.—On the 26th ult., at St. James's, Piccadilly, London, Francis Henry Laking, M.D., to Emma Ann, daughter of the late Joseph Mansell, Esq.
 PEACOCK-OGLIVIE.—On the 21st ult., at SS. Mary and Eanswith, Folkestone, Henry Peacock, R.N., M.R.C.P., F.R.C.S., of Gloucester, to Lucy Jemima, youngest daughter of the late John Ogilvie, Surgeon R.N., of Boughton-under-Blean, Faversham, Kent.

Deaths.

ARTHUR.—On the 19th Jan., Thos. Arthur, M.B., of Airdree, Lanarkshire, aged 30.
 DAVENPORT.—On the 19 Jan., Chas. Davenport, L.R.C.P.Ed., of Bromsgrove, Worcestershire.
 FRENCH.—On the 28th Dec., at Bhandara, C.P., India, suddenly, from bursting of a blood-vessel, Thomas E. French, Surgeon, Madras Army, Civil Surgeon of Bhandara, second son of Allen French, M.D., Bellary, co. Galway, aged 33.
 KEEL.—On the 23rd Jan., at Highfield Lodge, near Southampton, H. W. Keele, M.D., Staff Surgeon R.N., aged 84.
 REYNOLDS.—On the 12th Jan., H. W. Reynolds, M.R.C.S.E., of Thame, aged 72.
 SCOTT.—On the 6th Jan., Robt. Thos. Scott, L.R.C.S.Ed., Deputy Inspector-General of Hospitals and Fleets, of Melby, Shetland, aged 63.
 SHORTT.—On the 20th Jan., at 14 Belgrave Road, Rathmines, John Shortt, M.D., late Inspector-General of Hospitals, in his 92nd year.

DONEGAL DISTRICT LUNATIC ASYLUM, LETTERKENNY.—The Governors of the above Asylum will, on WEDNESDAY, the 10th FEBRUARY, 1875, proceed to elect a gentleman duly qualified in Medicine and Surgery, to act as Consulting and Visiting Physician to the Institution, at a salary of one hundred pounds per annum.

Applications, enclosing testimonials, &c., to be forwarded to Alex. Stewart Merrick, Esq., M.D., Resident Medical Superintendent.
 The personal attendance of candidates required on the day of election.
 (By order) HUGH STEVENSON, Clerk.
 Letterkenny, 27th January, 1875.

LECTURES ON HOMŒOPATHY.
 Instituted by the British Homœopathic Society.

A Course of Lectures will be delivered at the LONDON HOMŒOPATHIC HOSPITAL, Great Ormond Street, Russell Square, W.C., commencing on Thursday, February 4th, at 5 P.M., and to be continued on every succeeding Thursday until further notice. The course will comprise, firstly, Lectures on the History and Principles of Homœopathy, by Dr. R. E. Dudgeon; secondly, Lectures on Homœopathic Materia Medica and Therapeutics, by Dr. Richard Hughes; thirdly, Lectures on Clinical Medicine, by the Medical Officers of the Hospital.
 Members of the Medical Profession admitted on presentation of address card. Medical Students can obtain cards entitling them to admission on application to Dr. Bayes, Honorary Secretary to Lectures Committee, 68 Brook Street, W.

THE ROYAL HOSPITAL for DISEASES of the CHEST, City Road, E.C.—Notice is hereby given that the Council will meet on Tuesday, the 16th day of February now next ensuing, to examine applications from Candidates for the post of PHYSICIAN to the Hospital, vice Dr. H. B. Donkin, appointed to the Westminster Hospital. The Candidates must be Fellows or Members of the Royal College of Physicians of England on the day of election.

Applications, with testimonials, &c., to be forwarded to the undersigned by Monday, the 15th of February, of whom also any further information may be had.
 By order, C. LOWTHER KEMP,
 22nd January, 1875. Secretary to the Council.

TO MEDICAL MEN AND CAPITALISTS.—HOTEL AND CONVALESCENT SANITARIUM.—The Proprietors of a furnished Hotel, in one of the most fashionable and frequented Marine Resorts, on which about £18,000 has been expended, possessing sanitary advantages not to be surpassed, and having a well-established first-class hotel business, with a view to its extension, are desirous to treat with one or more persons who can command £20,000.

The special object proposed is to meet the particular requirements of the numerous Invalids and Convalescents who resort to the locality in a manner, to meet the cordial approval and patronage of the Medical Profession, for which there is every facility.
 Apply, in the first instance, by letter, to "MABINE," 41 Coney Street, York.

SURGICAL SOCIETY OF IRELAND.—The FIFTH MEETING of the SOCIETY will take place on FRIDAY EVENING, 5th FEBRUARY, 1875.

Chair will be taken at half-past eight o'clock precisely.
 B. WILLS RICHARDSON, F.R.C.S.I., } Hon. Secs.
 HUMPHREY MINCHIN, F.R.C.S.I., }
 Royal College of Surgeons, Dublin,
 25th day of Nov., 1874.

MIR. I. SANDHEIM,

Dentist,

16 SJFFOLK STREET,

DUBLIN.

N.B.—A Vacancy for a Pupil.

The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements, from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

The scale of charges is as follows:—

Seven lines and under	£0 4 0
Per line afterwards	0 0 6
One quarter page	1 5 0
Half-page	2 10 0
One do.	5 0 0

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

PATRON:—H.R.H THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £35 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote. Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c. can be had at the office,

40 MOLESWORTH STREET, DUBLIN,
W. O'NEILL, Secretary.

ACCIDENTS WILL HAPPEN!!

Provide against the Losses that follow by taking a Policy AGAINST

BREKLEY SQUARE, LONDON, W.

CAUTION.—Mr. BOURJEAUD respectfully cautions the Profession against advertisers who have assumed his inventions.

Ruptures. By Royal Letters Patent.

WHITE'S MOC-MAIN LEVER TRUSS

approved by upwards of 500 Medical gentlemen to be the most effective invention in the curative treatment of Hernia.

The use of a steel spring, so often hurtful in its effects, is here avoided; a soft bandage being worn round the body, while the requisite resisting power is supplied by the MOC-MAIN PAD and PATENT LEVER, sitting with so much ease and closeness that it cannot be detected, and may be worn during sleep. A descriptive circular may be had and the Truss (which cannot fail to fit) forwarded by post, on the circumference of the body two inches below the hips being sent to the Manufacturer,

JOHN WHITE, 228 Piccadilly, London.

Single Truss, 16s., 21s., 26s. 6d., and 31s. 6d. Post free.

Double Truss, 31s. 6d., 42s., and 52s. 6d. Post free.

Umbilical Truss, 42s. and 52s. 6d. Post free.

NEW PATENT

ELASTIC STOCKINGS, KNEE-CAPS, &c.,

for Varicose Veins, Weakness, and Swelling of the Legs, &c.

Prices 4s. 6d., 7s. 6d., 10s., and 16s. each. Post free.

JOHN WHITE, MANUFACTURER, 228 Piccadilly, London.

The usual discount to the Profession.

Established 1848.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE,

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S.,

&c. (KING'S COLL.), and Author of VIA MEDICA.

Has always upon his books a large number of desirable Investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

PRACTICES AND PARTNERSHIPS NOW OPEN for Negotiation (in addition to those advertised in Dr. Langley's List, which is sent post free on application).

Z 76. In one of the most fashionable watering places, a **PRESCRIBING PRACTICE for TRANSFER**. The receipts average upwards of £1,000 a year, and there is great scope for enlargement of the connection as the resident population and visitors largely increase every year. There is very little midwifery, and this only at high fees. No dispensing. The Practice is very transferable, owing to peculiar circumstances which could be fully described confidentially to an intending purchaser. The fees are 5s. to 10s. 6d. The residence is situate in the best part of the town; it is very large, in perfect repair, and fitted with every modern convenience. There is also stabling, coach-house, groom's cottage, &c., held on beneficial lease, of which five years are unexpired. The successor must be accustomed to good society, and should hold high qualifications, or possess undeniable experience in surgery and medicine. Terms dependent on length of introduction; but no gentleman can be negotiated with who cannot pay down £1,000.

Z 90. **PARTNERSHIP in a good COUNTRY PRACTICE** in a pleasant and rich agricultural district in the home counties, and within 60 miles of London. In consequence of the death of the senior partner there is a vacancy for a doubly-qualified gentleman accustomed to good society. The practice is very old established, and the actual receipts during the last three years average upwards of £900. Previous to the illness of the late partner the receipts were £1,300, and could be raised to that amount again. The incoming partner would rank as senior, and would take two-thirds of the profits. Appointments yield nearly £200. There is no opposition. The residence is large and convenient, with gardens and meadow land. Rent £30.

Z 87. **DERBYSHIRE. AN OLD-ESTABLISHED PRACTICE**, yielding £600 a year, for TRANSFER. Patients good middle-class. Usual midwifery fees from £1 1s. to £2 2s.; about thirty-five cases a year. Appointments yield £150. House contains twelve rooms, with stabling, coach-house, large garden, green-house, and land. Incumbent retiring from practice. Premium, one year's purchase, part of which may be left on security.

Z 92. **KENT. AN OLD-ESTABLISHED PRACTICE for SALE**. Receipts over £600 a year. The whole practice within a very narrow area. Appointments, £40; patients, good middle-class. The house is small, but convenient, contains eight rooms, and is held on lease at a very low rent. The Practice is chiefly in the suburbs of a large town, and there is considerable scope for increase.

LOCUM TENENS WANTED.—For fully-qualified gentlemen of experience and unexceptionable character, Dr. Langley can find constant employment on liberal terms. Apply **PERSONALLY** at 50 Lincoln's Inn Fields, as above.

ON NOXIOUS AND OFFENSIVE TRADES AND MANUFACTURES, (a)

WITH ESPECIAL REFERENCE TO THE BEST PRACTICABLE MEANS OF ABATING THE SEVERAL NUISANCES THEREFROM.

By H. LETHEBY, M.B., M.A., &c.,

Professor of Chemistry in the College of the London Hospital; late Medical Officer of Health and Public Analyst for the City of London; and President of the Society of Medical Officers of Health.

HAVING shown the intentions of the Legislature and the duty of medical officers of health in reference to nuisances, the author classified them under three heads, namely:—

1st. Those which are caused by the escape of noxious or offensive effluvia, as gases and vapours.

2nd. Those which are produced by smoke, dust, or other mechanical impurities.

3rd. Those which are occasioned by the discharge of noxious or offensive matters into gutters, ditches, or water-courses.

He then said: It will not be possible to discuss in a satisfactory manner the whole of these subjects in this paper, and therefore I propose to limit your attention to the first of them, namely, to those trade nuisances which are caused by the escape of noxious and offensive effluvia, as sulphuretted hydrogen, empyreumatic or other organic vapours, and the gaseous acids.

Foremost of those operations which cause offence by the escape of sulphuretted hydrogen into the atmosphere is the manufacture of sulphate of ammonia from gas liquor. This liquor is produced in great quantity at the gas-works—

varying from 10 to 40 gallons per ton of coals, according to the strength of the liquor and the perfection of the processes for removing ammonia from gas. The strength of the liquor is estimated and expressed by its gravity in degrees of Zwaddell, or by the number of ounces of strong sulphuric acid (sp. gr. 1,850) required to saturate a gallon of it. This varies from 5 or 6 ounces per gallon to 25 ounces, and, according to my experience, the proportion of sulphuretted hydrogen contained in it ranges from 230 grains, or rather less than one-third of a cubic foot of sulphuretted hydrogen per gallon, to rather more than 1,250 grains, or nearly 2 cubic feet per gallon; so that the liquor is exceedingly offensive from the quantity of sulphuretted hydrogen contained in it; and therefore it is necessary to store it in air-tight tanks, and to transport it from place to place in air-tight vessels—as barrels or tank-barges, or tank-trucks. It is proper also that the orifices which give exit to the air at the time of filling the tanks should be guarded with a box or small barrel containing hydrated oxide of iron, which absorbs the sulphuretted hydrogen, producing sulphide of iron which is subsequently dried and revived by the action of the air.

The methods of treating this liquor with sulphuric acid so as to produce sulphate of ammonia have differed at different times and places. In my early experience, even in this metropolis, the process was to neutralize the liquor with brown acid of specific gravity 1,720, and to convey the evolved gases into a furnace fire, as their escape into the air would be dangerous to the workmen; and the saturated liquor still reeking with sulphuretted hydrogen was evaporated in open lead troughs over open fires. The nuisance arising from these operations was absolutely unbearable; and as people got to be more and more sensitive of annoyance, the old process was discontinued. At the present time the practice is to evaporate or distil the liquor from closed boilers or chambers, and to convey the volatile products—ammonia, carbonic acid, and sulphuretted hydrogen—into a closed chamber, or saturator, containing weak sulphuric acid, there being a contrivance for the escape of carbonic acid and sulphuretted hydrogen, and the conveyance of them to a furnace fire. In some cases the liquor is distilled from boilers set over a common

(a) Part of a paper read before the Association of Medical Officers of Health on January 16, 1875.

fire; but, as this is liable to flushes and irregularity in working, it is objectionable, and has given place to the process of distilling by means of a steam coil set in the boiler by which steam at from 20 to 30 pounds pressure is blown into the liquor. But the best contrivance of all is that known as Coffey's still, which consists of a vertical chamber from 20 to 25 feet in height, having a series of transverse septa which alternately leave an opening at their ends. In this way, with about sixty of such septa, a superficial area of about 1,000 square feet of evaporating surface may be obtained. The liquor is delivered in a constant and graduated stream at the top of the chamber, and as it flows backwards and forwards in a descending current over the transverse septa, it meets with an ascending blast of steam which is let into the bottom of the chamber at a pressure of from 15 to 30 pounds. In this way the volatile constituents of the liquor are carried over to the saturator, where the ammonia is arrested by sulphuric acid, and the exhausted liquor flows out in a continuous stream from the bottom of the chamber. The saturator is generally an air-tight, leaden vessel, about 4 or 5 feet square and 3 or 4 feet deep, containing a charge of diluted sulphuric acid—equal parts of chamber acid (1,600) and water. When the acid is saturated with ammonia, which is known by test-papers, steam alone is blown into it for about half an hour to displace all traces of sulphuretted hydrogen, and the solution is drawn off into open pans or troughs, where it is evaporated by means of a closed coil of high pressure steam set in the solution.

Another kind of saturator occasionally in use is a leaden vessel divided into two compartments by a diaphragm or curtain, which descends below the liquid to within about 18 inches of the bottom. One of these compartments is closed air-tight and receives the volatile products of the still, where they meet with a graduated stream of brown acid (sp. gr. 1,720), which continually neutralises them, and forms crystals of sulphate of ammonia, which are constantly laded out of the open compartment. The apparatus is ingenious, and saves much labour and time in evaporation, as the acid is used in its undiluted condition; but it is not so certain or satisfactory in its action as the closed saturator before described.

In both cases the uncondensed gases—sulphuretted hydrogen and carbonic acid—with much steam, are conveyed from the saturator through a 4-inch pipe to the furnace fire, where the sulphuretted hydrogen is burnt. It is necessary, however, that the sulphuretted hydrogen should be deprived of its moisture before it reaches the fire, or it will extinguish it; and this is effected by throwing the pipe into coils, or otherwise cooling it. The precautions, therefore, to be taken in the conduct of this business are:—

1st. The transference and storage of the gas liquor in air-tight tanks guarded with boxes of hydrated oxide of iron.

2nd. The distillation of the liquor in a steady and continuous manner in air-tight stills by means of high pressure steam.

3rd. The saturation of the ammonia in close vessels, and the complete expulsion of sulphuretted hydrogen from the saturated solution before it is drawn off for evaporation.

4th. The condensation of moisture from the sulphuretted hydrogen evolved from the saturator, and the conveyance of the cold dry gas to the furnace fire where it is to be completely burnt.

5th. The treatment of the exhausted liquor from the still with cream of lime, so as to recover the residual ammonia by a second distillation; or, if the process be in operation at a gas works, the use of the residual ammonia as an absorbent in the purification of gas.

6th. The observance of the greatest care as regards the tightness of all parts of the apparatus.

Another operation which demands care in its management is *distillation of coal tar* for the various products derivable from it. There are two kinds of tar derivable

from coal, according as the temperature of distillation is high or low, and according to the richness of the coal in hydrocarbon. One is ordinary coal tar, and the other is the tar from which paraffin oils are obtained. The tar produced from common coals at a high temperature (common coal tar) is always heavier than water (sp. gr. 1,120 to 1,150); it dries freely in the air by oxidation; it contains hydrocarbons with such an excess of carbon that they cannot be burnt in a common lamp; it is almost entirely destroyed by strong oil of vitriol; it contains much sulphur, and its percentage composition is about 86 carbon, 7 hydrogen, 6.5 oxygen, and 0.5 sulphur. Whereas the tar produced from cannel coal at a low temperature is lighter than water (sp. gr. about 900); it will not oxidate or dry in the air; it contains hydrocarbon of the paraffin series which are comparatively poor in carbon, and which can be burnt in a lamp; it is not much acted on by oil of vitriol; it contains little or no sulphur, and its percentage composition is about 84 carbon, 12 hydrogen, and 4 oxygen. Each of these tars is the subject of technical manipulation, and if not properly managed are the cause of nuisance, as are also the processes used in their primary production. In dealing with ordinary coal tar, it is proper that it should be stored and carried in air-tight tanks, and left covered with a little water. The delivery of it into the tank barges or tank trucks, and from them into the tanks of the works, should be by means of pumps and air-tight flexible hose, and the openings of the barges and tanks should be guarded with a box containing hydrated oxide of iron, as in the case of ammoniacal liquor.

The distillation of coal tar is always conducted in iron stills set over a naked fire—the stills are of varying capacity, from 1,200 to 5,000 gallons, and the crown of them is always protected with brickwork to keep them hot, so that the later volatile products may not cool and condense and fall back into the still. The time of the distillation of a charge is from twelve to fifteen hours, according to the capacity of the still, and the products are first condensed in a worm or pipe kept cool in water, and are received into a specially contrived box (varying in form and construction at different places) which permits the several products to flow away by separate pipes (four or five in number, and each provided with a tap) to their several tank receivers. This box is made air-tight (its cover being guarded by a water valve), and it is provided with an ascending pipe, which carries the foul gases to proper purifiers before they pass into the furnace shaft. The gases which are evolved during the process of distillation are, first sulphuretted hydrogen from the ammoniacal liquor which always accompanies the tar, then gaseous or uncondensable hydrocarbons, and finally the acid vapours of the superheated pitch with an abundance of sulphuretted hydrogen. These gases and vapours should be made to pass, first through a vertical condenser or scrubber charged with a stream of cold water, and then through an oxide of iron purifier with two or three trays of oxide, and finally to the furnace shaft. The necessary draft for these operations should be secured by means of a fan or by the aid of the furnace shaft. It is proper to mention, that unless there is a draft of considerable power, the unavoidable leakage from the constantly loosening joints of the pipes will not be prevented. It is right also to state that it is dangerous to convey these gases and vapours into a furnace fire, as they are explosive when mixed with air, as they necessarily will be.

The products of the distillation of coal tar vary in different places. At one time they were but four, namely:—First, ammoniacal liquor and very light naphtha, which come over before the tar in the still begins to boil. Second, a crude naphtha, which floats upon water, and is therefore called "light oil." Third, a creosote oil, which sinks in water, and is called "heavy oil;" and fourth, the residuum, which is a soft pitch. At present, however, in well-conducted works, the creosote or dead oil is run off in two portions, namely, an early portion, which is a mixture of

creosote and heavy naphtha, which is used for burning in furnaces; and a later portion, which is best suited for the preservation of timber. This is followed by a greenish oil, which is sometimes collected apart, and redistilled with the anthracene oil that runs from crude-pressed anthracene; and then follows a green oil (anthracene oil), which is allowed to flow until it gets very thick from the presence of chrysene. It is in the later stages of the process, when the high temperature of the still causes the decomposition of the pitch, that sulphuretted hydrogen and acrid vapours are evolved; and this also is the cause of the nuisance from the hot pitch when it is run off from the stills into open pits. To guard against this, it is proper that the fire should be raked out from under the stills directly the process is over, and the pitch should remain in the stills to cool for ten or twelve hours; it should then be run into close receivers, or into a properly constructed chamber, and allowed to cool for twenty-four hours before it is discharged into the final receiver. All these should be ventilated so as to convey the vapours through the scrubbers and purifiers before mentioned. An excellent form of receiver for the pitch from the stills is a long air-tight chamber, which will bear internal pressure, and which communicates at the bottom with an outside trough, into which the cool pitch is forced by the weight of the hot pitch at each time of its discharge from a still. The pitch when cooled to a temperature of about 180° or 190° Fahr. may be freely exposed to the air, and be either run into pits or ladled out into moulds.

It may be interesting to know that the approximative yield of the several products per 1,000 gallons of coal tar is as follows:—

Crude and light oil, sp. gr. 940 to 970	from 24 to 40 gals.
Creosote oil	1,060 „ 1,070 „ 120 „ 180 „
Anthracene oil.....	1,080 „ 1,095 „ 100 „ 160 „
Pitch which melts at 170° Fahr.	3.2 to 3.6 tons.

These products are again submitted to further operations for the purpose of getting benzole, toluol, light burning and solvent naphthas, carbolic and cresylic acids, creosote for fuel and for timber, and anthracene; but the processes are not generally offensive, and therefore need not engage much of our attention, although a brief outline of them may be useful. The light oil is redistilled from stills with steam jackets or with closed coils, or by blowing steam into it. That which flows up to a gravity of 940 is put aside for benzole and solvent naphtha, and the remainder is used for carbolic acid. The naphtha thus obtained is purified by treating it with strong sulphuric acid, and then washed with lime water, and distilled for benzole and solvent naphtha. The heavier naphtha, and the first runnings of creosote are washed with a solution of caustic soda for carbolic acid, which is subsequently separated from the alkali by neutralization with acid; and the green anthracene oil is allowed to stand until quite cold, when the crude anthracene separates from it in granular particles. This is strained off through canvas bags and pressed in hydraulic or screw presses, whereby the crude anthracene of commerce is obtained. The approximative yield of each of these several products is:—

From crude naphtha and light oil from	6 to 10 per cent. tar acid.
Ditto ... 20 „ 28 „	benzole.
Ditto ... 10 „ 15 „	solvent naphtha.
Creosote oil ... 10 „ 15 „	carbolic acid, &c.
Anthracene oil 10 „ 12 „	crude pressed anthracene.

For the purpose of increasing the yield of anthracene the distillation of the pitch is sometimes carried on until a spongy coke remains in the still, and under these circumstances the acidity of the evolved vapours is most offensive, and requires the utmost attention to prevent their becoming a nuisance to the neighbourhood. The main points, therefore, to be observed in the conduct of works of this description are:—

1st.—The transport and storage of the coal tar in air-tight tanks or vessels guarded with boxes containing hydrated oxide of iron.

2nd. The proper construction of the primary receiver of the products of distillation, so that it may freely deliver them by special pipes to their respective receivers, and at the same time convey offensive non-condensable products to the scrubbers and purifiers.

3rd. The passage of the offensive non-condensable gases and vapours to a scrubber charged with a douche of cold water, from thence to an oxide of iron purifier, and thence to a tall chimney shaft.

4th. The proper cooling of the pitch in air-tight vessels before it is allowed to reach the external atmosphere, and the ventilation of these vessels through the scrubber and purifier before mentioned.

5th. The use of a fan or other exhausting power, so as to draw all the noxious gases and vapours from the stills, the pipes, the receiver, and the pitch den, into and through the scrubber and purifier before mentioned.

The production of paraffin oil from cannel coal, and the distillation of the crude tar, as well as the distillation of petroleum and Rangoon oil, requires like precautions, though not to the same extent, as the products are not nearly so offensive as in the case of coal tar products.

Dead oil or creosote is largely employed for preserving timber; but unless there is great carelessness in the management of the operations they are not offensive. The process is conducted in the following manner: The timber to be creosoted is placed in iron cylinders of great strength and capacity, and when the end opening is closed and well secured with screws, the interior of the cylinder is exhausted by means of an air-pump until there is a vacuum of only about 5 inches of mercury. This is maintained for nearly half an hour, during which time the contents of the cylinder are heated by steam pipes. In this manner the air and moisture of the wood are drawn out of it, and dead oil is then allowed to run into the cylinder until it is full. The heat is continued, and pressure is put upon the contents of the cylinder until it reaches to from 100 to 150 lbs. upon the square inch. This is maintained for many hours, the time varying from 4 to twelve hours, according to the nature of the work; in most cases the amount of creosote absorbed by the wood ranges from 40 to 50 gallons to the load of 50 cubic feet. The oil is then run out, and when sufficiently drained the timber is ready for delivery. Hardly any precaution is necessary beyond that of preventing the unnecessary escape of creosote oil and vapour.

Dead oil is also used as fuel, and there are two ways in which it has been successfully employed. In one case the oil is converted into vapour in a specially contrived boiler, and the vapour is burnt as fuel. In the other the creosote is delivered from a jet immediately over a steam jet, and as the creosote trickles down from the upper jet it meets the blast of steam which blows it as a fine spray upon a bed of glowing cinders or ashes. In this manner it produces a sheet of flame of great heating power. A ton of creosote, which is about 210 gallons, is equal to about two tons of ordinary coals; but the management of the jet or stream of creosote is rather a delicate operation, as an excess of the oil produces an immense volume of smoke, with the acrid irritating odour of the unburnt oil.

Before leaving the subject of these hydrocarbons, I may state that the *melting of pitch and asphalt* for the production of materials suited for the making of asphalt pavements, &c., is in the generality of cases a very offensive operation. All sorts of pitchy matters, as the residuum of paraffin oil (technically called "shellgrease"), Trinidad bitumen, various natural asphalt, and coal tar pitch are melted in small iron boilers set over naked fires. The boilers are but loosely covered, and during the melting and mixing, to produce the material called "bitumen," large volumes of irritating and offensive vapours escape into the air. The bitumen thus produced is, in some cases, again heated with powdered asphalt in specially constructed boilers having a mixer moved by machinery, and in this case offensive vapours are freely evolved. The charge when thoroughly incorporated and melted is called

"mastick," and is drawn off into pails, and cast in moulds for use where the pavement is to be laid. All these operations should be conducted in closed boilers, which should be ventilated by a fan through a scrubber prior to its entrance into the chimney shaft.

The clarification of oil for burning and other purposes is generally effected by means of sulphuric acid, which is well stirred into it. After the black flocculi, formed by the action of sulphuric acid upon impurities, have subsided, the oil is further clarified by means of water and steam, the latter being blown into it until it reaches a rather high temperature, and during this part of the operation the oil is kept in gentle agitation by means of stirrers so as to favour the separation of the oil from water and other impurities. In the case of rape or colza oil, the vapours which are given off are disagreeable and acrid, like mustard, while those of linseed and other oils are also offensive, though in a less degree. Cotton oil is refined by means of a solution of caustic soda, and this also, when subsequently heated, is offensive. The remedy in each case is the carrying on of the operations in closed vessels, ventilated to the furnace fire.

The distillation of oils and fats for the production of stearic, margaric, palmitic, oleic, and other fatty acids is effected by means of sulphuric acid and superheated steam. The melted fat is run into vats or boilers, where it is heated to a temperature of about 240° Fahr. At this temperature it receives a dose or charge of strong sulphuric acid, delivered into it as a fine spray, or through perforated copper trays. All this time it is kept in continual agitation by means of stirrers, and this is prolonged for about an hour, during which time a little sulphurous acid and acroleine escape. When the fat acquires a dirty greenish tint the "saponification," as it is called, is complete. Boiling water is then run into the mixture and steam blown through it for about four hours; after this it settles for a couple of hours, and the acid watery portion is run off. It is washed a second time with hot water and steam, and when clear it is delivered into the stills for treatment with high-pressure superheated steam—the pressure being about 50 lbs. on the inch, and the temperature about 500° Fahr. At this temperature and pressure the fatty acids are distilled over, and collected in a series of condensers, ending in a worm set in cold water. The first condenser delivers the greater part of the fatty acids with but little water, the second more water and less acid, and so on to the end, where water is the chief product. The water contains glycerine, and the residuum in the stills is a sort of pitch, which is used by the asphalt makers.

In these operations sulphurous acid and acroleine are evolved so as to be offensive to the neighbourhood, unless they are conveyed from air-tight apparatus into the furnace fire.

Oil boiling for making varnishes, linoleum, leather-cloth, printers' ink and black japan, is a very disagreeable operation, and requires to be conducted in boilers from which the fumes pass into the furnace fire to be destroyed.

Varnish making and rosin distilling are also offensive operations, and necessitate the destruction of the acrid organic vapours by carrying them to the furnace fire, or to fires placed at the outlet of hoods which cover the pans. In cases where inflammable spirit is used to a large extent in certain manufactures, as in making American cloth, the difficulty of dealing with the vapour is exceedingly great, as it is dangerous to pass it through a furnace fire for fear of explosions. In one factory with which I am acquainted, the quantity of petroleum spirit used daily in the thinning of the oil for the colours is not less than 140 gallons—all of which is daily evaporated from the cloth in the drying room, which is gradually raised to a temperature of 130° Fahr., at which it is kept for six hours during the drying of the colours. In these cases it is best to ventilate the room freely by special shafts communicating with the chimney at a point where the vapours are not likely to be fired.

Fat melting, bone boiling, tripe dressing, and the cooking of sheep's heads, bullocks' cheeks, livers, and feet, as well as the boiling of shellfish, lobsters and crabs, are all offensive operations, and require to be conducted in closed coppers ventilated by special flues, which carry the organic vapours into the fires beneath them.

SUPRA-CONDYLOID AMPUTATION OF THE THIGH. (a)

By WILLIAM STOKES, F.R.C.S.,

Professor of Surgery Royal College of Surgeons; Surgeon to Richmond Surgical Hospital.

ALTHOUGH I have had on a former occasion the honour of bringing under the notice of the Surgical Society the subject of supra-condyloid amputation of the thigh, the results I have recently obtained, and the high opinion that is held of the procedure by some operating surgeons of well deserved eminence, both in this city and in England, induce me again to draw the attention of the Society to the advantages which I am of opinion may be reasonably claimed for the operation.

Before alluding to the cases, the particulars of which I wish briefly to mention this evening, I desire to exhibit a series of casts which show fairly the results I have obtained in seven instances after this operation; and through the kindness of our able secretary, Mr. Richardson, I can also submit to the Society a cast showing an admirable result which he obtained after this procedure. I regret that it is not in my power to show one of a stump in a case that was operated on by this method by my eminent colleague Professor Macnamara, but I trust that it may be exhibited to the Society on a future occasion. I shall now, as briefly as possible, mention the leading particulars of the last two cases in which I performed this operation.

CASE I.—Michael Walsh, æt. 28, by occupation an ironmonger, was admitted in the Richmond Surgical Hospital under my care on the 8th of last August, having been recommended by Dr. Allman, of Westport. The first appearance of the disease from which he suffered, necrosis of the upper third of tibia preceding chronic synovial inflammation of the knee-joint, was in the year 1870. The patient stated that in that year several pieces of bone came away through various sinuses situated on the anterior and internal aspects of the upper portion of the shaft of the tibia. In the following year the knee became affected. In 1874 he was admitted into the County Infirmary, and there amputation was suggested to him, but at that time he would not consent to the operation proposed. He then came up to Dublin, and was admitted into Richmond Hospital.

At the time of his admission the sinuses I have already spoken of had healed, and what appeared chiefly to call for surgical treatment were the synovial effusion and thickening. For some time I entertained the hope that by rest, vesication, iodine, and the internal exhibition of antistrumous remedies I might possibly succeed in saving the limb. I accordingly put the limb up in a gypsum bandage, adopting the Bavarian method as advocated by Dr. Corley, and followed out the treatment I have already alluded to, into the details of which I need not now enter. This I continued for nearly two months, and then finding that no improvement had taken place, but rather the reverse, the sinuses having re-opened and revealed the existence of extensive osseous disease, I recommended amputation. As there was no evidence that the disease had involved either the patella or lower end of the femur, the case appeared specially adapted for supra-condyloid amputation, and this operation I accordingly performed on the 7th of last October, Esmarch's bandage having been applied, and chloroform administered. The operation was as bloodless as it was painless, and I may mention here an observation

(a) Read before the Surgical Society of Ireland, January 22. The discussion will be found at page 119.

made by my late revered colleague, Mr. Adams, on this occasion. It was "the first time," he said, "in which I have witnessed an amputation of the thigh during which the patient did not give a single moan, or lose a single drop of blood."

As regards the steps of the operation, I may mention that, save in one particular, to which I shall presently draw attention, I followed rigidly the rules mentioned in former communications on this operation made to this Society and to the Medico-Chirurgical Society of London. As regards the progress of the patient after the operation, there is nothing that is noteworthy, except that the union of the wound was exceptionally rapid.

CASE II.—The next case was also one for which the operation of supra-condyloid amputation was performed on account of extensive necrosis of the bones of the leg.

John Maloney, æt. 25, by occupation a draper, was admitted into my wards in the Richmond Hospital on the 2d of last November, having been recommended to me by Dr. Ryan, of Ballynacally, co. Clare. The patient stated that about nine years ago he experienced a sudden and violent pain in the right leg, immediately below the knee. For his he was unable to assign any cause, never having received any injury to the leg, and previous to the first occurrence of the pain, always having been healthy. In about a month after the occurrence of the pain, an abscess formed, which opened, and from which there was for several months a copious discharge of matter. About twelve months after this several pieces of bone came away. The openings then closed, and the patient continued tolerably well until about a year previous to his admission into hospital, when the pain and discharge commenced with increased severity. The whole shaft of the tibia appeared, more or less, engaged in the disease. At the original opening immediately below the tubercle of the tibia, there was a large and loose sequestrum, the removal of which was effected a few days after his admission into hospital without any difficulty.

As the disease was so very extensive, nothing short of amputation was ever contemplated by me, and I removed the limb on the 11th November, adopting the supra-condyloid method of amputation.

Nothing untoward occurred during the convalescence of this patient, and the result may, I think, be said to be satisfactory, although the stump cannot be said to be quite as shapely as that obtained in Walsb's case. All the main advantages, however, which I think may be claimed for this operation can be observed in the result.

Before discussing these advantages I desire very briefly to draw attention to the operations at, and in the immediate vicinity of the knee, which preceded supra-condyloid amputation, and of which the latter operation is the outcome.

To Professor Velpeau is undoubtedly due the credit of first pointing out the advantages to be derived from amputation at the knee. Among these may be mentioned that the weight of the body can be placed on the face of the stump, that the hip-joint preserves all its movements, and the patient need not walk as if that joint were ankylosed, and that the shock is not so great as after the ordinary amputations of the thigh.

The modifications of this operation introduced by Professor Syme and Mr. Carden, and the details of which procedures it is unnecessary for me to discuss on the present occasion, were the next that were introduced into surgical practice, and subsequently the modification of Carden's operation, which is known in Continental schools chiefly as Gritti's amputation, and, lastly, the operation to which I desire to draw attention this evening.

I may mention that the steps of Gritti's procedure I learned many years ago from Professor von Langenbeck, of Berlin, and details of it I have also learned from papers by Melchior and Prof. Rizzoli, of Bologna, whose excellent work on clinical surgery reflects high credit on himself and on the school of which he is a distinguished member. What the date of Gritti's original memoir (if he ever wrote one) is, I have not been able to determine, but as I find Melchior's first case of Gritti's amputation was in 1851,

the original suggestion must have been made previous to that year. This I have learned from Prof. Rizzoli's surgical memoirs. Melchior's case was of a man whose leg had been crushed by the wheel of a locomotive. The bone was sawn on a level with the condyles, and, as might have been expected, the patella was soon drawn away from the cut surface of the condyles, upwards on the anterior surface of the bone. The second operation, performed by Melchior was in 1866. In consequence of the great and unavoidable tendency of the muscles to draw the patella away from the cut surface of the femur, Melchior and Gritti applied paste-board splints round the stump immediately after the operation, forming a kind of box, or *étui*. It is not surprising to learn that this method of operating, and subsequently treating such cases, was found unsatisfactory, and attended with a high rate of mortality. The tendency to the occurrence of profuse suppuration and gangrene which was observed next induced Prof. Rizzoli to modify the operation. Being of opinion that leaving the synovial membrane was one of the causes of these disastrous consequences, he first disarticulated the knee as Gritti had done, then removed the synovial membrane, did not remove the articular surface of the patella, and divided the femur a little higher—he does not say how much. This operation, though in some respects an improvement on Gritti's and Melchior's, does not commend itself to me for these reasons. In the first place, the preliminary disarticulation must add greatly to the shock of the operation; secondly, the removal of the synovial membrane is not only unnecessary, but mischievous, for retaining it as a lining of the anterior flap, must I think, diminish largely the chances of purulent absorption; and thirdly, not splitting the patella is a serious defect, as not doing so must greatly diminish the chances of union between the two bones. Whether the femoral section was above or below the upper margin of the cartilage of incrustation does not appear. But it is of the utmost and most paramount importance that the directions in reference to this point should be clear, accurate, and definite; for the success of the operation depends, I may say, altogether upon the situation of the femoral section. If it is below the point I have indicated in former communications on supra-condyloid amputation—namely, from one-half to three-quarters of an inch above the antero-superior margin of the cartilage of incrustation, the patella will inevitably be tilted forwards during the healing of the wound, unless, perhaps, the unsurgical and dangerous device of boxing up the stump tightly in pasteboard splints be adopted. If, on the other hand, the section be made too high, the medullary canal will be opened and the dangers of the operation will be largely increased, and the split patella will hang down and be on a lower level than the cut surface of the femur.

In the fourth and fifth cases I operated on I observed, even when the femoral section was made at the point I have indicated, a tendency to subsequent tilting forwards of the patella; and I determined that in the next case I operated on I would take steps, without dividing the bone higher up, to secure that there should be no shifting of the bone from its moorings. This I accomplished in my sixth and seventh cases, the two that are now before the Society, by stitching the bones together with carbolised catgut. In doing so I passed the needle, armed with the suture, through the tissues immediately adjacent to the centre of the posterior margin of the femur and through those immediately above the centre of the inferior edge of the patella, and on fastening the ligature the two bones were kept in close apposition. Both ends of the carbolised suture were cut short and left in the wound, and in the course of some days were doubtless absorbed. But before that took place the patella had, so to say, become accustomed to its new position and to be already partially united to the femur. I do not mean to convey that this method should be adopted in all cases; but when the patient is a well-nourished muscular adult there is, even when the high femoral section is made, a tendency on the part of the extensors to tilt forwards the patella, and in

such cases the carbolised catgut suture is indicated, rendering as it does "assurance doubly sure."

I may now briefly state the advantages that I think may be claimed for supra-condyloid amputation, which name I have selected in order that surgeons should bear in mind the necessity of making the femoral section *above* and not through the condyles, as in Syme's, Carden's, and Gritti's amputations. These advantages are, those which it has in common with the other amputations at the knee, and those which are peculiar to itself. Among the former I may mention—

1. The stump being more useful for progression in consequence of the possibility of making pressure on its extremity, and the patient not being obliged to walk as if he had an ankylosed hip-joint, as is always the case when the point of support is at the pelvis. As Dr. Marké says: "To the poor man this single circumstance makes all the difference, between his being able to earn his living by active employment and his being laid up for life a hopeless cripple. To the rich man who is able to secure the aid of an artificial limb, it makes the difference between a point of support at the knee and a point of support at the ischium. In fact, it is practically the difference between amputation below and amputation above the knee."

2. The diminished liability to the formation of tubular sequæstræ.

3. The operation is less hazardous, being further removed from the trunk than the ordinary amputations of the thigh.

4. The shock is less than in the higher amputations, as the muscles which are divided are few in number, and being cut, not through their fleshy bellies, but at their tendinous extremities.

5. Less liability to suppuration.

6. Less liability to osteo-myelitis, from the medullary membrane not being interfered with.

The special advantages of supra-condyloid amputation are—

1. That the posterior surface of the anterior flap is bound with a natural synovial lining, which I feel confident largely diminishes the chances not only of subsequent exhaustive suppuration, but also of purulent absorption.

2. Any possibility of the split patella shifting from its place on the cut surface of the femur is prevented by the high femoral section, and by stitching the two bones together in the manner I have described.

3. The existence of an osseous curtain, which is formed by the split patella covering the cut surface of the femur, diminishes probably the chances of pyæmia, and is not liable to slough away as the periosteal curtain as recommended by Von Langenbeck undoubtedly is.

4. The vessels are divided at right angles to their continuity, and not obliquely, as they are in other flap operations.

5. The existence of a posterior flap diminishes the chances of any wide gaping of the wound posteriorly, while the anterior flap, being oval, increases the chances of the stump tapering gradually towards its extremity and assuming the form of a rounded cone.

6. The preservation of the normal attachments of the extensors of the leg.

To Professor Velpéau is due the credit of first recommending the preservation of the patella in amputations at the knee-joint, and this recommendation was adopted subsequently by Lane, Blenkins, and Marké. To Gritti is due the credit of drawing attention to the fact of the great advantage that is derived from having the patella fixed, in order that there should be a firm standpoint on which the extensors may act. The operation, however, as practised by him, was in many respects a defective procedure, was attended, as Prof. Rizzoli informs us, with a high rate of mortality, and consequently soon fell into disrepute. It has been asserted that the credit of priority in Gritti's idea should be given to M. Seymanowski. This opinion is based on an observation in M. Sedillot's work on operative surgery. The statement is not correct, and is

characteristic of the inaccuracy which is so often observable in the writings of our French *confères*.

In supra-condyloid amputation, which is the outcome of the procedures I have alluded to, notably those of Velpéau, Carden, Gritti, and Rizzoli, I have endeavoured to retain the advantages observable in these operations, and to eliminate what experience has shown to be defective in them, and the results obtained in my hands, and in those of the eminent surgeons in this city and elsewhere who have practised the operation lead me to entertain the hope that it may be conceded hereafter that in supra-condyloid amputation an advance has been made in operative surgery. It may be said that it is premature in me to hold the high opinion I do of this operation. Still I can point to the fact that as yet the mortality after the operation in Ireland has been *nil*. I may mention, too, that one of the eminent surgeons of the Leeds Infirmary, Mr. Wheelhouse, considers that the method possesses "advantages which render it in many cases decidedly superior to any other known method of amputation of the limb, and which render its adoption almost, if not quite, imperative." This opinion was given in 1872; and wishing to know in what estimation the operation is still held in Leeds, I wrote to my friend Mr. Jessop, one of the first, if not the very first, who practised the operation in England, and he observes: "The supra-condyloid amputation fully maintains its repute here. I see no reason whatever to alter the opinion I expressed to you some time ago as to its merits. Whenever a suitable case presents itself I prefer it (the supra-condyloid) to Carden's, as well as to all other forms of amputation in the immediate neighbourhood of the knee-joint."

Every surgeon, too, to whom I have shown the results obtained by this procedure has borne evidence as to the shapeliness of form in the stumps, and their applicability for the subsequent adjustment of prosthetic mechanical appliances. Professor Macnamara and Mr. Richardson, both of whom have amputated by this method, will, I feel confident, endorse much, if not all I have said in favour of the operation. In conclusion, I would again express the hope that eventually surgeons will concede that, of thigh amputations, as regards form, appearance, and applicability to the adjustment of prosthetic mechanical appliances, supra-condyloid amputation affords the most satisfactory results, and, more important than all, is the operation of its kind which is attended with the minimum of risk to the patient's life.

THE DISSECTION OF THE EYE

By C. H. GOLDING BIRD, M.B., B.A. Lond., F.R.C.S.,
Demonstrator of Anatomy at Guy's Hospital.

THE usual methods of dissecting the eye, as described in the text-books of anatomy, though well calculated to display the several component parts, require, however, so much care and manipulative skill satisfactorily to accomplish, that the study of the eyeball is in many cases conducted solely upon paper, and the requisite knowledge of it for examinations acquired from books and lectures. In order to obviate somewhat this state of things, and to render the dissection of the eye as simple as possible, the following instructions have been drawn up, to follow which the most inexperienced dissector need find no difficulty, while nothing of importance for all ordinary purposes will remain unexamined if proper care be employed.

The whole can be studied upon one eye-ball, though a second would be advantageous, and the only instruments required—not usually found in the dissecting-case—are a camel's hair brush, an ordinary glass slide, and a glass tube drawn into a capillary point, which is preferable to a blow-pipe, however fine.

The dissection is supposed to be carried out upon a bullock's eye. Should the human eye be employed, allowance for the difference of size should be made.

I. Clean from fat and muscles, study the shape and general appearance of the eye-ball.

II. Holding the eye in the left hand, make with a sharp scalpel a small incision into the sclerotic, parallel to, and about half an inch from, the edge of the cornea, of such a depth that the black choroid is seen.

III. Now insert one blade of a pair of scissors into the aperture, piercing at the same time both choroid and retina being careful not to wound the hyaloid membrane) and cut through all three coats, completely round the eye-ball in the lateral meridian, keeping always the same distance from the cornea.

IV. Place the eye, with the cornea downwards, in a vessel of water, and on seizing the optic nerve and making traction, the weight of the vitreous will cause it to separate into two portions: the anterior, containing the cornea, lens, vitreous, &c., the posterior, the back part of the shell of the eye. Each will have to be studied separately, and during the examination of the posterior part, let the anterior remain undisturbed under water.

A.—OF THE POSTERIOR PART.—(i.) Fill the cup-like cavity with water and let it rest in the palm of the hand; in it may now be studied the fundus of the eye, *e.g.*, optic disc. (ii.) Holding it in the same position, remove with forceps the retina; the inner surface of the choroid will be exposed. (iii.) Now turn the "cup" inside out over the tip of the forefinger of the left hand, and, commencing at the circumference, detach, with a camel's hair brush moistened, the choroid from the sclerotic. The ciliary nerves and vessels, as fine threads, lying in grooves in the lamina fusca that lines the sclerotic, and passing to the choroid, are seen during this process. (iv.) Remove the choroid by cutting through its attachment around the optic nerve, and placing it in water, float it on to a slip of glass, with its external (*i.e.*, sclerotic) surface uppermost. With a camel's-hair brush remove the pigment cells from the surface, and, on holding it up to the light—still resting on the glass, the *venæ vorticosæ* will be seen. (v.) To complete the study of the sclerotic after the lamina fusca has been examined, divide it longitudinally through the centre of the optic nerve; on the surface of this section, at a point where the nerve pierces the sclerotic, the lamina cribrosa may be seen.

B.—OF THE ANTERIOR PORTION.—(i.) Whilst resting upon the vitreous under water, the cornea being uppermost, seize on either side with forceps the cut edges of the sclerotic and choroid, being careful not to include the retina. Raise the eye by means of the forceps thus applied. The vitreous, lens and capsule, and anterior portions of retina, with the suspensory ligament and canal of Petit will fall *en masse*, and remaining in the forceps will be the cornea, choroid plexuses, iris, and anterior part of sclerotic. (ii.) In this latter part study *in situ* the choroid and its plexuses and the posterior aspect of iris. Then brush off the pigment cells from the choroid, and detach it from the sclerotic by raising its cut edge with a scalpel; continue this till the point of its attachment to the sclerotic is seen. This is marked by a white line, the ciliary muscle. A cut across in another part will show a transverse section of the same, and at the junction of the cornea with the sclerotic, the aperture of the canal of Schlemm (*syn. sinus circularis iridis*) may be seen. The inner boundary of this canal is formed by the ciliary ligament, or ligamentum pectinatum. (iii.) As a final step the laminae of the cornea may be stripped off. (iv.) The remainder of the eye (vitreous, capsule and lens, &c.) removed from the water must be turned, so that the lens rest uppermost, and to keep it in this position pass some long pins obliquely through the vitreous into a piece of wood or cork, on which it is advantageous that the specimen should be placed. On examination there is seen, immediately surrounding the lens, a clear space, and then an exact imprint of the choroid plexuses on the suspensory ligament of the lens (*syn. zonule of Zinn*), and still more externally the milky-white retina appears, unless it happen to have become detached. (v.) Insert a fine capillary tube into the clear ring surrounding the capsule (*i.e.*, perforate

the innermost edge of the suspensory ligament). On inflating, the clear ring will swell into the sacculated, or beaded, canal of Petit, which is thus seen to be formed in front by the suspensory ligament of the lens, and behind by the hyaloid membrane of the vitreous. (vi.) Incise the capsule, slight pressure suffices to extrude the lens, while the space left shows how the latter was implanted in the anterior surface of the vitreous humour. Rubbing the lens between the thumb and finger will demonstrate its hard central or nuclear portion.

If a lens be kept a few days in alcohol, the peculiar arrangement of its laminae can be seen.

The anterior chamber is the space that exists between the back of the cornea and the front of the iris. The posterior chamber is between the iris and suspensory ligament of the lens.

The positions of the several parts mentioned, and their exact relations to one another, should be examined, if possible, in another specimen that has been frozen, or hardened in alcohol, by means of an antero-posterior vertical section.—*Guy's Hospital Gazette.*

Hospital Reports.

METROPOLITAN FREE HOSPITAL.

(Under the care of Dr. CHARLES R. DRYSDALE)

Smoker's Tongue.

A MAN, aged 53, consulted Dr. Drysdale for his tongue which for some time past had given him some annoyance. He was married, had several children. Never had any symptoms of venereal disease. Had been a very heavy smoker, smoking often all day long, and consuming as much as an ounce of shag tobacco daily for weeks together.

The tongue was fissured at the edges; in the middle line, and for half-an-inch on each side of it, extending from the circumvallate papillæ until about half-an-inch from the tip, there was a wide strip of white striated, looking patches over the tongue, greyish-white in colour, and slightly harder than the other parts of the tongue to the touch. A very weak solution of nitrate of silver painted over the tongue gave a somewhat similar aspect.

Diagnosis.—Smoker's tongue.

Treatment.—To abandon tobacco, if possible, and use tannate of glycerine and nitrate of silver occasionally to the tongue.

Remark.—There seem to be three periods in affections of the tongue caused by tobacco-smoke. The first is merely simple erythema, and the mucous membrane becomes red, and loses its polish. If carried on further, the epithelium becomes white, thickened, and softened, and comes away in scales, presenting a whitish patch, rather like syphilitic mucous plates. Lastly, these patches become cracked, and an ulcer, painful, and with greyish base and irregular edges, is seen. The edges may become hard, so hard as even to simulate, in rare cases, hard chancre. There can be no doubt, too, unfortunately, that such patches occasionally are apt to degenerate into epithelioma. Many cancers of the lips and tongue are due to smoking. Who can deny it? Women are infinitely less subject than men to white patches in the mouth (psoriasis). Is this not an additional proof that tobacco is an exciting cause of such patches? Consider the acidity of the juice of tobacco-smoke, the heat of the short pipes used, the abuse of spirituous liquors, &c., so frequent in old smokers, and the deplorable condition of their teeth in so many instances.

Yet, on the other hand, it is certainly true that, in proportion to the number of great, very great smokers, the number of cases of patches of the tongue is very small indeed. As usual, then, we must trust a little to convic-

tions, and we can only say that we believe that white patches on the tongue, *psoriasis* or *tylosis*, are more frequently due entirely to tobacco than is believed.

Case of Tinea Decalvans.

THE following case of alopecia areata is one among many seen at this hospital where a cure has taken place after persevering treatment for months by cantharides. Dr. Drysdale is inclined to believe that in many cases there is a parasite present, and leans to the belief of Dr. Bazin on this point.

Abraham Barnett, *æt.* 15 years, came to the Metropolitan Free Hospital on May 22nd, 1874. He is of the Hebrew persuasion. For the last two or three months he has noticed his hair come off in patches from the right side and top of head when he combed it. He is a maker of cigars. He does not know that he has caught it from any other boy. Baldness extends from the edge of the parietal bone back to the middle line of the occipital bone, and from the vertex to the ears. On the left side of the head there is a space of about three or four inches, commencing at the vertex, and also a portion on the left parietal bone. He was painted with liquor epispasticus for four months.

June 16, 1874.—Has been blistered all over the head, and in consequence of this there is some appearance as if new hairs were coming up on the bald spots.

January 23, 1875.—The hair is now quite thick all over the head except one spot on the right squamous portion of temporal bone.

INDIAN MEDICAL NOTES.—No. XXXI.

(FROM OUR SPECIAL CORRESPONDENT.)

MEERUT, *December, 1874.*

THE PNEUMATIC ASPIRATOR—EARLY TAPPING—SCARLET FEVER—AGUE.

On the last night of the old year the pen idly lags whilst the scribbler builds in thought the castles over again, sorts the cards, speculates, calculates: if he had only done this, if he had only played that, or to adopt the argument professionally, if in certain cases the treatment had been more decided, or, on the contrary, less heroic, *perhaps*—but the wave has passed beyond recall; the failures, the sorrows, the miserable anxieties of 1874 cannot be remedied now; still, as the sailor learns his business in the storm and tempest instead of idling in smooth water, so in India the practitioner, ever battling with deadly diseases, trusts in better luck for the future, on the old adage of the silver lining to every cloud. There are notes upon notes on the table telling of fever, dysentery, hepatitis, and all the insidious dangers connected with malaria; but in breaking health and broken spirits, as poor Lever said, I cannot enter into any calm detail this night of the old year, when somehow all ideas run into the saddest grooves. In a previous paper it was mentioned how a distended bladder was relieved by the aspirator; it is satisfactory to relate that in diagnosis of tumours, in evacuating deep popliteal abscesses, in tapping for hepatic dropsy, in relieving a strangulated oblique inguinal hernia, the pneumatic aspirator answered admirably. In the hernia case we were called from dinner to a native whose symptoms of two days' suffering were becoming urgent; the stereotyped measures so far futile, until the introduction of a fine needle let out a little gas, about a teaspoonful of fluid, when, presto! the hernia, a small one, was reduced without the slightest evil result. Contrast this with hours of agony, the torture of the taxis, the risk of operative interference, the danger of delay. So soon was the business over that we drove back to our guests, who wondered at the doctors returning so soon with such radiant faces. In hepatic dropsy, suppose the patient an old drunkard, with a history of facial paralysis, a feeble heart, a green, bloated, grog-blossomed countenance, tense, shining, distended, painful abdomen, swollen legs, equally painful, with a tale of wasting dyspnoea, dyspepsia, epistaxis,

hæmaturia—let me, from the satisfactory results of a recent case, advise early tapping, next work away at the cause—probably the liver—using the aspirator; do not forcibly attempt by more pumping to agglutinate secreting surfaces together after evacuation of fluid; rather trust to iodide of potassium, bandaging, and medicine, eventually not forgetting, directly after the operation, to inject morphia in warm water hypodermically over the liver or spleen, as it were to anticipate peritonitis; also quinine and ipecacuanha are useful medicines in their proper places. We may have to deal with cirrhosis, with purpura depending on arterial degeneration of fatty character, with impending apoplexy, as threatened by pasty, stolid, purple, puffy face, blinking eyes, and guttural speech. There may be structural hepatic disease impeding return of blood through portal vein, possibly also splenic enlargement, valvular disease of the heart of rheumatic origin. Unless the skin can help, the end by coma may suddenly supervene, for the weakly coats of the cerebral vessels will only stand a certain amount of strain. What are we to gain by diaphoretics, cathartics, diuretics, warm baths, when the brain, heart, lungs, liver, kidneys are tried to the utmost, when diarrhoea, bleeding piles, ulcers, epistaxis, hæmoptysis indicate the amount of obstruction? Granted that tapping takes away a certain amount of albumen—what is the use of that albumen where it is? for the pressure of the fluid cuts off a new supply, besides preventing the healthy chemical change. Tapping early relieves the kidneys, the albumen subsiding from the urine, relieves intra-portal pressure, promotes absorption, facilitates a new line of circulation, and also the dangers of typhoid exhaustion are anticipated. Supposing the patient has renal, cardiac, or hepatic disease, or we have to deal with a tumour as the cause, this need not deter the early tapping, a method of treatment now earnestly advocated, for if you do it early the operation need not be repeated, whereas in the later stages you tap and tap until the patient dies. Years ago a different opinion would have been expressed; then we trusted to past traditions, when the aspirator of Dieulafoy was unknown. Years ago a poor woman, after months of treatment by a herbalist, applied for relief for enormous abdominal distension, necessitating paracentesis to the extent of several buckets full; but the operation had been delayed too long, she died that night. A symptom of extreme alarm and danger is that of abdominal meteorism, to be satisfactorily dealt with by the introduction of the long tube, by enemata of turpentine, opium, and assafetida, the bowels poulticed and bandaged. Enemata should invariably be used to relieve constipation succeeding enteric fever, for if you trust to strychnine by the mouth the remedy may play tricks unexpected, may cause violent pain involving straining which may tear open the treacherous ulcers only just healed, or may even start fresh mischief. For intractable diarrhoea, sometimes an injection of perchloride of iron, ipecacuanha, tincture of opium, a drachm of each in solution will be of service, also suppositories, say a drachm of ipecacuanha combined with three grains of belladonna; but on one occasion, when five grains were used, the patient, relieved of agonising griping, showed all the symptoms of belladonna poisoning—burning of the throat, dilated pupils, red eruption, delirium, tottering gait, spectral illusions, and for some time after vision was impaired.

Concerning scarlet fever, just a word: Depending on cold air, turpentine and castor-oil draught, followed by a mixture containing dilute nitro-hydrochloric acid; I certainly would leech the throat, and have the patient frequently rubbed all over with carbolised oil; never mind the smell or the dirt, the smell of carbolic acid is less offensive than that of scarlet fever. It is not a bad idea to have hot bottles about the feet and loins, also to rig up a suit of coat and trousers all in one, of coarse flannel, to be worn at night, when the patient is liable to chills, as he flings off all covering. Common sense, milk diet, the thermometer, the urine tests, will all assist, and the wet sheet be a true friend if the heat, delirium, skin, or kidneys be unmanageable. There are

dangers about cold affusion, the belief being that bed-sores, just as a crop of boils, may thus be provoked. In certain cases mercurial inunction may be expedient; in the majority of cases, leeches to the throat and nitro-hydrochloric acid imperatively necessary, and of the wet sheet no praise is too lavish. The experience of years, of thousands of cases, points to the necessity of quarantine, of burning everything, if possible, of disinfecting excreta, and of using tents whenever practicable, for the poison clings indefinitely to houses, and if you allow a patient to flee from home to a hotel, look out for legal proceedings, ending in heavy damages. The most susceptible are pink-faced, pretty, intelligent, precocious children, and although infants at the breast may escape, the rule is not absolute, neither does previous sickness, nor do pregnancy, familiarity with disease, nor old age confer immunity. No one can guarantee that the practitioner in attendance on scarlet fever is safe in the midwifery room; it has been one's fate on several occasions to stand in this uncertain position without bad results, but the pitcher may go to the well once too often; and there's no disease more easily communicable, no disease of greater danger and uncertainty than scarlet fever, which in certain places, for instance, Jullunder, Newshera, Mean Meer, Sealkote, Umballa, has run on sometimes from January to August, the admissions highest in July. There are very many points of similarity between enteric and scarlet fever; so there are in the treatment, for instance, the use of leeches, bodily inunction, the wet sheet, mercurial inunction; yet there is a wide difference in the nature of the eruption, the malignant throat, renal and dropsical complications, the desquamation, and above everything, the virulence of contagion. This year, watching the men who had enteric fever some time ago, it is noticed they suffer just as much as the others from ague, with tendency to splenic enlargement. Intermittent pulses, alarming functional epigastric bruits, stupidity, neuralgia, rheumatism, debility, fortunately pass away. Everybody knows the complications the sequelæ of malarial fevers, syncope, diarrhoea, dysentery, hepatic or splenic mischief, dyspepsia, fatuity, impotence, jaundice, rheumatism, scurvy *inter alia*; yet writers say little of the temporary general dropsy some patients suddenly develop, most curious in its appearance, as a rule subsiding after warm baths and diaphoretics.

Tartar emetic, nitrate of potash, chloride of ammonium, jalap, chiretta, podophyllin, opium, iron, quinine, last, but not least, are the remedies for fever. Quinine in small and frequent doses for a length of time, or else hypodermically, say five grains of the neutral sulphate dissolved in warm water (20 minims) injected under the scapula, and not again until the next attack, taking care the syringe is clean, may be very valuable, indeed acts like a charm, but not always, for deaths by tetanus and ugly ulcers have occurred in the experience of the most careful discriminating practitioners. The natives believe in tea; the old soldiers in hot grog; and in England people have no idea of the comfort of iced brandy and soda at one time, hot whisky and water at another, that their friends in India so thoroughly enjoy. Mental influence here has little effect on controlling ague, for the player on the stage, the rider in the circus, the man interested in anything, escapes not—as hysterical people do who, by incantations, cob-webs, fried mice, magic rings, candle-snuff, dancing around the church communion table at midnight, or wearing sacramental plate over their stomachs, have been cured, or else by repeating certain texts, and heaps of other expedients.

Writing becomes suddenly interrupted by the inspiring sound of military music this clear, cold, glorious night, welcoming the New Year, so the thread of composition is lost in a series of sad recollections conjured up by the soul-stirring strains of "Auld lang syne."

SIR DUNCAN GIBB says that an old woman, aged 112, has just died at Tring, in Hertfordshire. She was baptised at Chinnon, in Oxfordshire, in 1763, on April 24.

Transactions of Societies.

THE SURGICAL SOCIETY OF IRELAND.

THE Society met on the evening of Friday, the 22nd January, Mr. TUFNELL, the President, in the chair.

Mr. WILLIAM STOKES read a paper on
SUPRA-CONDYLOID AMPUTATION OF THE THIGH,
which will be found at page 114.

In the discussion which followed

The PRESIDENT observed that, according to Professor Stokes, paper, he had performed six amputations by this new method, which would otherwise have been amputations of the thigh, and there had been no mortality. That was a degree of success which spoke most favourably for the operation.

Dr. B. F. McDOWELL said: I have another case of supra-condyloid amputation to add to those which Professor Stokes has brought forward, and I may say that I was highly pleased with his singularly able paper, and he may feel proud of the success which has followed his operations. My case was that of a man, 65 years of age, who was admitted to Mercer's Hospital in March, 1872, nearly three years ago. He was suffering from an epithelial ulcer of the leg about the size of a crown piece. I endeavoured to destroy the ulcer by caustics, such as chloride of zinc and others, but failed, and I then decided on removal of the leg; but when the operation was proposed he refused to submit to it, and left the hospital. In the month of September following he returned to hospital, looking emaciated and wretched. He had had successive attacks of bleeding from the ulcer, which had extended enormously, and he suffered from constant pain and loss of sleep. Being an old man, very much emaciated and anæmic, it was doubtful whether any operation should be performed. I endeavoured, however, to save his life, and he himself was most anxious that something should be done. The question then was, what operation should be performed? Certainly, any operation about the thigh would be more dangerous than one below the knee. On the other hand, one performed below the knee would be attended by such a loss of blood and consequent shock as I am perfectly sure in this case would have precluded the possibility of the man's recovery. I therefore determined to operate near the joint, and I performed a modification of Carden's operation. I reflected a long anterior skin flap, convex in shape, and reaching to the insertion of the patella; I then, contrary to Carden's method, reflected a small posterior skin flap, and having by a circular sweep of the knife severed the tendinous extremities of the muscles, I sawed off the bone just above the condyles. The operation might be said to be absolutely bloodless—the man was so anæmic; it was like dissecting on a dead body. He made an excellent recovery; he has a sound serviceable stump, and the cicatrix is posterior, and quite free from harm. The man is now 67 years of age, and was recently in excellent health. As the great majority of amputations of the thigh have been hitherto performed in the upper third, and as the operations in the vicinity of the knee, such as that of Carden or that now described by Mr. Stokes are, in my mind, likely to be followed by a lesser degree of mortality than the former, and to give a more serviceable stump, I cannot but feel that the adoption of the supra-condyloid amputation in suitable cases would be an advance in our art. I should have stated that in my case the medullary canal was not opened. (Dr. McDowell exhibited a photograph of the case).

Dr. CORLEY said that within the last three or four months he had performed Carden's operation. It had often been said about the Dublin School of Surgery that they were slow to accept innovations, and although he had heard of Mr. Stokes' method of operation some years ago, he was not prepared to perform it in accordance with Mr. Stokes' directions, because he had not seen any of those cases, and was not sufficiently acquainted with the subject. It had been roughly estimated that every inch of the femur removed gave an additional mortality of ten per cent. He was, therefore, impressed with the importance in these amputations of going as near to the knee-joint as possible. He had seen the operation known as Syme's modification of Hoin's amputation, and did not see much advantage from it, and he therefore made up his mind, if a case arose, to perform Carden's operation through the condyles.

Of all those amputations before the plan brought forward by Mr. Stokes, Carden's was the easiest performed, and gave the best results. He had, however, been so much struck with what Mr. Stokes had said about his operation that he would at once adopt it with perhaps some modification. In Carden's operation through the condyles there are two very ugly and projecting pieces of bone, whereas, having made several experiments on the subject, he believed Mr. Stokes was perfectly safe in going one-fourth or three-fourths of an inch above the condyles without opening the medullary canal. Carden's operation, however, left two ugly projecting points, necessitating the performance of a secondary operation, and perhaps the rounding off of the inferior edge, otherwise the edge of the flap would be brought in contact with the end of the femur by the contraction of the muscles, and the consequences of this might be imagined. Mr. Spencer, who operated in this way, applied strips of plaster on each side to obviate this danger—the forcible dragging of the flap against the edge of the femur. In his own case he (Dr. Corley) had to put on two strips of plaster to keep off the pressure, but by Mr. Stokes' modification this pressure on the flap was obviated, and so far the operation was an improvement. There was a difficulty in maintaining the patella in its place, and he would suggest whether a section of the rectus and crureus tendons might not remedy that, and do by natural means what Mr. Stokes endeavoured to do by stitching.

Professor MACNAMARA: I had an opportunity of hearing, some time ago, Mr. Stokes' description of his operation, and it struck me as valuable. Some time before he brought it forward I performed an amputation by Syme's plan, and I well remember the length of the flap that had to be made posteriorly. It was a long time before a case came under my notice requiring amputation through the knee-joint, and impressed by Mr. Stokes' statement, I called on him and asked him to rehearse to me the various steps of his operation. When he spoke of splitting the patella I own I thought it a most unfavourable point in the operation; nevertheless, taking his advice, I performed the amputation according to his plan, and that which I had conceived to be the great difficulty, the splitting of the patella, was performed without any difficulty by that useful instrument, Butcher's saw. It was a case full of doubt, full of suspicion, and giving rise to the most unfavourable prognosis. The lady was broken down in health, the victim of erysipelas, and if ever a surgeon had a case to approach with foreboding, it was that one. It is now two years since the operation was performed, and the lady is alive and well. A case of that kind speaks trumpet-tongued in favour of what may be now properly termed Mr. Stokes' supra-condyloid amputation through the knee-joint.

Mr. H. G. CROLY said he had listened with great pleasure to Mr. Stokes' paper, and the results could not be more satisfactory. He would ask, why did they amputate through the knee-joint at all? He had performed many thigh amputations, and the greater number of them were for diseased knee-joints, and it struck him that this operation was more suited for disease of the bones of the leg than for diseased knee-joints. In the amputation of the thigh low down by the rectangular flap operation, introduced by Mr. Teale, the mortality was greatly reduced. He (Mr. Croly) never lost a patient by Teale's operation, and he had operated in a good many cases, and the statistics of the City of Dublin Hospital for the last sixteen years showed that the mortality had been extremely small; indeed, he remembered but one death occurring during that period from a thigh amputation. While he was satisfied that Mr. Stokes' method was a good one in cases where the leg was diseased, he did not think it could ever take the place of amputation at the lower third of the thigh.

Mr. B. WILLS RICHARDSON observed that Mr. Stokes, in his history of this operation, stated that Sédillot was wrong in giving the credit of the operation to Seymanowski. Unfortunately, Sédillot did not give in his "Traité de Médecine Opératoire," published in 1865, the date at which it was suggested by Seymanowski, and until we got that we could not say whether Seymanowski or Gritti had originated the operation. Within the last few days a friend of his, Monsieur Perrève, had an interview in Paris with Monsieur Sédillot on the subject, who told him that he saw Monsieur Seymanowski's suggestion of this operation in some journal, of which he could not recollect the name. He (Mr. Richardson) might here observe that Sédillot himself did not approve of the operation. With regard to the difficulty of sometimes retaining the patella in its new position, he (Mr. R.) anticipated that in his operation by long anterior and short posterior flap, which he per-

formed in October, 1870, (a) and divided the tendon of the rectus muscle at the time of the operation. Theoretically, one would say that that would weaken the command of the stump; but practically it did not, and he (Mr. R.) never saw a more useful stump than resulted from that operation, the cast of which was on the table. He would rather adopt that plan than pass a ligature, as Mr. Stokes suggested, through the thin remaining portion of the patella left after the removal of its articular surface.

Dr. QUINLAN asked whether in any of Mr. Stokes' cases he had a diseased patella to deal with.

Mr. STOKES replied: He did not wish to be understood as meaning that this operation should supersede any of the other methods of amputation to which attention had been directed by himself and other speakers. He preferred supra-condyloid amputation to Carden's operation (a modification of which had been performed by Dr. McDowell) because in the latter, owing to the great thinness of the anterior flap there was a special tendency to slough, and in the University Hospital, London, he had seen no less than three cases of Carden's operation in which sloughing of the anterior flap occurred. With reference to the section of the rectus which Dr. Corley suggested in order to obviate the necessity for bone sutures, he (Mr. Stokes) preferred the latter method, inasmuch as he believed the division of the muscles would necessarily result in weakening them, and ought, therefore, to be avoided. Professor Macnamara's observations were important as showing that he had experienced so little difficulty in splitting the patella, and also because of the successful result of the operation in one of the most unfavourable cases he (Mr. Stokes) had ever seen. Mr. Croly was right in stating that this operation was mostly applicable in cases where the disease was referred to the bones of the leg. In the second of his cases there was extensive disease of the soft tissues of the knee, and he did not think that the existence of disease of the knee, provided it be confined to the soft tissues, was a reason why the operation should not be performed. He was satisfied there was much less risk in it than there would be in excision. With reference to the claims set up for Seymanowski as the originator of this operation, he could not find any justification for it. In the great Continental hospitals in Vienna, Berlin, and elsewhere, where he had come into contact with famous physicians, he never heard of M. Seymanowski or of his operation. Sédillot's statement was very vague; it contained no description of the operation, and was characteristic of the loose way in which French surgical writers dealt with these matters. M. Sédillot must have known that the credit of retaining the patella and advocating its preservation to stand as a fixed point for the muscles to act on belonged to Gritti and to no one else, and he ought therefore, when mentioning Seymanowski's name in connection with this operation, to have given a precise statement of what that gentleman had done, and the date of the performance. The title of supra-condyloid amputation was important as showing where the bone was to be divided. In reply to Dr. Quinlan, he had to say that he had not operated in any case in which a patella was diseased.

Professor MACNAMARA: It is most remarkable that there should exist so great a contrast between the mortality after capital amputations in England and that which followed similar operations in Ireland. I have performed a great many capital amputations, and I never lost a patient; and I appeal to the experienced surgeons present whether it is not the fact that death after amputations in Ireland is the exception! In England, however, we read of the deaths being one in three or four. The Vice-President of the College, who has had a large experience, tells me he scarcely ever remembers seeing a death after amputation. Professor Macnamara here read from Sédillot's work the following observations of his regarding the operation and Seymanowski: "M. le docteur Seymanowski has proposed to saw off the articular face of the patella, and to apply it against the divided extremity of the femur, without touching the tendon of the triceps crural muscle, to better secure direct sustentation upon the stump. This procedure, an imitation of that of Pirogoff, does not appear to us to merit great confidence, but the idea is very ingenious."

Dr. STAPLETON observed: I have operated in a great many cases, and I have never lost a case after amputation of the thigh.

The Society then adjourned.

(a) Recorded in the *Dublin Medical Quarterly Journal of Science*, for November 1871.

THE MEDICAL SOCIETY OF DUBLIN.

THE fourth meeting of the present session of this Society took place on Wednesday evening, January 18th,

DR. HENRY KENNEDY in the Chair.

Dr. McSWINEY communicated to the Society a paper on

CASES OF CHRONIC SIMPLE ULCER OF THE STOMACH,

in the course of which he pointed out that this was a painful, dangerous, and sometimes a fatal disease, which was met with chiefly in young females between 16 and 26 years of age, and the features of which physicians had to be well acquainted with in order that they might distinguish it when they met it and treat it successfully. Having traced the history of the disease from the time—1830—when it was first distinctly recognised and described by Cruveilhier down to the present time, he proceeded to read some cases in which he had diagnosed the existence of this lesion. The first case was that of a young woman, æt. 23, a French polisher by occupation. Four years ago she had distress of stomach after taking food, loss of appetite, and suffered from various dyspeptic symptoms. These were succeeded by epigastric pain, nausea, and thirst. The pain was ensiform in location. To believe it, she lay with the abdomen and face under. Food made the pain much worse, more particularly solid food. After some weeks of suffering she was suddenly seized with a violent attack of hæmatemesis. From this she slowly recovered in some weeks, after which she remained well for two years, when again there was a recurrence of all the dyspeptic symptoms under which she in the first instance laboured, and again she had a large vomiting of blood. When received into hospital she was weak and pallid, and the lightest pressure in the epigastric region immediately below the ensiform cartilage caused exquisite pain. She loathed food, and was wretchedly depressed and nervous. Whatever she swallowed, solid or liquid, caused pain, and was immediately rejected by vomiting. Alcohol in any form made her worse, and everything, even the blandest food, was vomited. She was placed under treatment, and at the end of four or five weeks left the hospital, being at the time apparently quite restored to health. Three other cases, in all important particulars similar to the one just related, were also reported by Dr. McSwiney. Finally, he reported a case by way of contrast to the others, in which many of the symptoms simulated upon superficial observation those of gastric ulcer, but which he had differentiated upon the occasion of first examining the woman carefully. Shortly, the woman was of a nervous temperament, and had been highly excitable, according to her own account, for years. Amongst the symptoms of which she complained was regurgitation of food, which occurred at irregular intervals. At this time she was free from pain in any part of her body. This food-vomiting came on chiefly at the catamenial periods, which were scanty and irregular. She suffered from leucorrhœa after months, during which she suffered from this regurgitation of food, pain, according to her account, began to be experienced, but this pain was variable in situation—referred now to one point and now to another, and was uninfluenced by food. Two months ago she stated that she vomited everything she took, and that the vomited matter contained blood, and she showed what purported to be an admixture of food and blood to the practitioner who was in attendance upon her. All this time, however, she remained in good condition; she was not in the least weak or wasted, nor had she the appearance of a person suffering pain. Somehow an idea had got about that she had ulcer of the stomach, and she appeared willing to favour this view. A thorough investigation of this case caused Dr. McSwiney to conclude that, notwithstanding the vomiting of food mixed with blood and the pain complained of, the case was not one of gastric ulcer at all, but should be referred to the category of hysterical affections, and he stated that, in point of fact, what occurred when the food was brought up was more analogous to ruminating than to vomiting, and referred to the graphic description of this affection given by Sir Henry Marsh in his well-known article in the *Dublin Journal*, as well as in his letter to Dr. Little. Dr. McSwiney next directed attention to the diagnosis which he had ventured to arrive at in these cases, and explained that, whilst he recognised the impossibility in some cases, and the difficulty in others, of arriving at a positive diagnosis of gastric ulcer, he claimed at the same time that under certain circumstances that diagnosis could be surely and unhesitatingly made. The grounds for arriving at this

diagnosis he declared were supplied by certain important symptoms which, when present, could denote no other malady. These symptoms were—pain, vomiting, derangement of the digestion, and hæmorrhage. In addition, he stated that the age, sex, and, in his opinion, the state of the menstrual function, afforded valuable aids towards perfecting the diagnosis. Having at some length remarked upon each of these heads, he next proceeded to discuss the etiology of the disease, referring to the labours of Rokitsansky, Virchow, Pavy, and others who had advanced knowledge on the subject to its present stage. Finally, he recapitulated the number of items of treatment which he had been accustomed to rely upon. It was as follows: *Regiminal*—He enjoined rest in bed, and secured the repose of the stomach by allowing only small quantities of nutriment to be taken, with long intervals between. Such nutriment consisted of milk with soda-water, or lime-water, and clear-strained beef-tea. *Medicinal*—He prescribed opium to allay pain, gallic acid to arrest hæmorrhagic or other discharges, and bismuth in a formula which he recited to arrest and cure the ulcerative process. He expressed an opinion that bismuth in the form of the liquor bismuthi possessed something approaching a specific curative action in gastric ulcer, and he suggested that this might be due to the alkalinity of the solution, which restored, perhaps, the equilibrium in the chemical economy of the gastric processes which had been disturbed by the initiatory pathologic changes which determined the formation of the gastric ulcer.

Dr. QUINLAN said he had a case in St. Vincent's Hospital which bore out a great many of the remarks Dr. McSwiney had made. It was that of a young girl, 20 years of age, who had been engaged at sewing-machine work in England, and had seen a great deal of hardship. She was sent over to this country with very little hope of recovery, in fact, to die, and when she came to hospital she was suffering from very great pain in the epigastrium. Whenever she took food she suffered intense pain, had much vomiting, the latter occasionally containing quantities of blood, but there was no purulent matter. The only thing he found gave her relief was the subcutaneous injection of morphia, which was done twice a day until she died. On opening the stomach they found near the pylorus a number of patches containing vascular injection. In this case he thought there was no ulcer; but he thought that if she had lived a little longer there would have been an ulcer, as the process was initiated. Her monthly hæmorrhages had been quite regular, and only ceased from debility.

Dr. EUSTACE inquired whether the attitude of the body assisted regurgitation in these cases.

Dr. McSWINEY replied that he knew of a case in which, when the body was placed in a certain position, regurgitation almost immediately took place.

Dr. GRIMSHAW had under his treatment a case similar to those mentioned by Dr. McSwiney. The patient had many points of interest. She had been watched for several years—first, by Dr. Head, and since by himself. She was twice under Dr. Head's care in the Adelaide Hospital. On the first occasion she got perfectly well, and on the second had improved so much that she left the hospital of her own accord, and returned to service in the county Kildare. She, however, got ill again, and vomited some blood, and suffered from intense pain in the epigastric region. She was coming up to town to be placed once more under treatment at the Adelaide Hospital, but got very ill in the train, and on her arrival at the Kingsbridge terminus vomited a large quantity of blood. In so serious a condition was she that she was brought by the railway porters to Mme. Stevens' Hospital, where she came under his (Dr. Grimshaw's) observation. There was some difficulty in arousing her from the state of collapse into which she had fallen, but in about twenty-four hours she was sufficiently recovered to be able to tell her history. As she said she had been treated by Dr. Head previously, he consulted with that gentleman as to the peculiarities of her case. While under his care scarcely anything was administered by the mouth at all. Medicines were given her in the form of pills, and food almost entirely by the anus. He (Dr. Grimshaw) adopted the same treatment, and the girl improved for some time until she was able to sit up, and afterwards she walked about the wards and corridors of the hospital. In fact, so satisfactory was the change in her, that he had hoped to be able to send her home in a short time. Before, however, she could leave, she had another attack of the vomiting of blood, and the pain returned. She recovered again

from this to a certain extent, and got almost into the same condition of convalescence as before, being able to walk about the hospital. She also regained flesh, having been previously very much wasted. She again relapsed, however, and this occurred three or four times, until she had spent altogether ten months in hospital. Having got somewhat better, but wishing to keep her under observation, he sent her to the Convalescent Home at Stillorgan. During his absence from town he received a letter from the matron of that institution requesting me to readmit the patient into Steevens' Hospital, as all the symptoms had returned. She again got as bad as ever, and afterwards improved, and again relapsed, and at the present time she was in hospital. The success which so frequently attended the treatment was somewhat remarkable. Food was administered by enemata, but any nourishment taken by the mouth was fluid—nearly all milk—and she was also given tonics. She improved under that treatment, and also experienced relief from small blisters placed over the stomach and dressed with morphia. The best means of allaying the pains were by the hypodermic injections of morphia administered three times a day when she was in the greatest suffering. Concerning the connection that was supposed to exist between this disease and intra-uterine affections, he might mention that in this case the menstrual functions were not regular, but unusually irregular. That circumstance did not, however, throw much light on the case, as, after a careful examination by an obstetric physician, no disease could be discovered. Next to the vomiting, that symptom of which the patient most complained was intense pain in the back, which was particularly well-marked. The girl was now wasted to a frightful extent, and there was only just as much flesh on her as would be consistent with life. She gradually gained flesh as some of the symptoms subsided, but when they returned she resumed her emaciated condition. Once or twice she had been subjected to fits, not purely of an epileptoid character. At first he thought the girl suffered from hysteria, but now he was of opinion that it was a case of gastric ulcer, in which he thought there had been repeated attacks of fresh ulceration, each new attack being a return of the disease. It was, however, the most protracted case of the kind he had ever met with. He had seen other cases with similar symptoms, but he never saw a case where the symptoms lasted so long and so frequently occurred as in this particular instance. He thought the case was almost incurable; but certainly Dr. McSwiney's paper led one to believe that sometimes more could be done with these cases than there was frequently reason to expect.

Dr. T. HUGHES, in the course of a few brief observations, said he was afraid that they had yet to look for the symptoms which would guide them to truth in diagnosing ulcer of the stomach, or else it was a very curable disease.

Dr. T. MORE MADDEN said that he thought Dr. McSwiney in his valuable paper attached rather slight importance to the connection between gastric ulcer and menstrual irregularities. He (Dr. Madden) thought in many of those cases that the menses were generally irregular. He had seen cases of hæmorrhage from the stomach, evidently originating from ulcer, in which there had been marked menstrual derangement. A short time since he attended a young lady from the country who came up to town to be placed under his care. She had been two years without menstruating, and suffered intense and constant pain in the stomach, with dyspepsia. On one occasion she had a fearful attack of hæmatemesis, the blood filling and overflowing a large basin. She came up to town to try every means to obtain a restoration of the catamenial discharges, and was seen by several obstetricians with that object. She returned to the country, and shortly afterwards, in response to a telegram, Dr. More Madden proceeded to her residence, where he found that she had had a return of the hæmorrhage, the menses at this time still continuing absent. A short time after this, however, menstruation returned, the gastric pains subsided, and she improved in health. This state of things, however, did not continue long, for the menses again ceased, and the gastric pains returned, and she suddenly died of the hæmatemesis. At present he had a lady under his care whose changes had stopped, who had gastric pains and repeated attacks of hæmatemesis. He had seen cases of young girls whose menstruation had become suppressed who had dyspeptic pains after food and occasional attacks of hæmatemesis. There could in his mind be no doubt of the occasional connection between all the symptoms which had been so well described as indicative of gastric ulcer and disordered menstruation. He thought their plain course in such

cases was to endeavour to restore the menstrual courses, besides following the general treatment which Dr. McSwiney had so well pointed out.

Dr. FITZPATRICK thought there was not the slightest connection whatever between ulcer of the stomach and suppressed menstruation. He felt they were very much in the dark on the subject to which Dr. McSwiney's paper was devoted—a paper that was most valuable in creating a discussion and leading to the investigation of a disease which was most mysterious and difficult of diagnosis. He thought the most important step was to ascertain whether or not the vomiting was caused by the presence of indigested matter in the intestine.

Dr. CROLY had seen cases where there was very little doubt of ulcer of the stomach, and the recorded cases and specimens in museums and the pathological reports he thought showed very clearly that ulcer of the stomach was not so unusual a disease. With regard to the vomiting symptoms, he thought that the explanation of them might be given in these cases such as had been given in cases of malignant disease. It was well known that if ulcer of the stomach occurred near the centre and apart from the orifices the symptom of vomiting was by no means a standing symptom. If they were to believe in the diagnosis of any cases where they did not make a post-mortem examination, surely they could believe, if a young woman had constant pain in the back and front of the stomach, there was scarcely anything else would produce these symptoms but ulcer of the stomach. With regard to the treatment, it struck him whether, in some of the cases mentioned, the internal administration of nitrate of silver might not prove of advantage, giving the stomach as much rest as possible from food, but occasional enemata. He thought they could not doubt that ulcer of the stomach was a curable disease from the results of the cases brought before the Society.

Dr. GRIMSHAW remarked that he had applied nitrate of silver in these cases.

The CHAIRMAN said he had seen a great number of instances in which certainly, even if ulcer of the stomach existed, the persons were now in complete and perfect health. In some of these cases there was very marked uterine complication. He presumed hæmorrhage in some of these cases came from the ulcer. He had met with cases where one or two leeches had done a good deal of service. He knew of the case of a female who had been relieved by the use of hemlock. She received no other treatment except as to regulating the bowels, diet, &c., and she got perfectly well. He also knew of a man who had all the symptoms of ulcer of the stomach who was relieved by the same means. He thought the difficulty of diagnosing ulcer of the stomach was greater than many would suppose. It was certain that the symptoms of the disease would be present and not the disease; and on the other hand, they might have ulcer without, comparatively speaking, any of the symptoms at all.

Dr. McSWINEY said, in further reply to Dr. Eustace, that in cases of gastric ulcer he endeavoured to trace the situation of the ulcer, and then to ascertain what effect position had on vomiting, but he could trace nothing. He did not think vomiting was dependent upon the situation of the ulcer. When the food was taken into the stomach it was followed by such annoyance to the patient that she rose into a sitting posture and used every means in her power to get rid of the food, and it was utterly impossible to ascertain whether position had anything to do with the vomiting or not. In the course of his concluding remarks, Dr. McSwiney fully admitted the difficulty of diagnosis in cases of gastric ulcer.

The Society then adjourned.

THE PATHOLOGICAL SOCIETY OF DUBLIN.

The usual weekly meeting of this Society was held on Saturday, January 23rd,

Dr. HENRY KENNEDY in the Chair.

TUMOUR OF THE FEMALE BREAST.

Dr. McSWINEY exhibited a tumour that was removed eight or ten days previously from the female breast. The subject from whom it was removed was a woman, æt. 50 years; she was

unmarried, and had ceased to menstruate six years previously. The history of the case was, that about the very period when the menstrual pause occurred she noticed the presence of a wart immediately adjoining the nipple of her right breast. She observed that this wart gradually increased in size, grew large, and eventually became pendulous; but as it gave her no inconvenience of any sort whatever, she did not consult anyone about it, in fact, she never showed it to anyone, but carefully concealed it until she consulted him about it. Her reason for seeking advice was, that about seven or eight weeks previously it had commenced to be troublesome. It was not that it gave her pain, for there never was pain either in the tumour or breast, but the tumour became sore, and at its terminal point or bulb an abrasion of the cuticle or covering took place, and there exuded from it a muddy-coloured fluid, which was evidently serous in character, as it stiffened the linen which was wetted by it. When he saw the tumour it was pendulous in character, and altogether about six or seven inches in length, and equally divided between the pedicle and bulbous extremity, the latter measuring between five and six inches in circumference. The pedicle sprang from the areola, and included the greater portion of the nipple of the breast. It was of normal colour. Taken between the finger and thumb a considerable artery might be felt pulsating, and conveying a sensation similar to that produced by the umbilical cord in a recently born infant. It was about the diameter and size of this structure when of its normal dimensions. The bulbous extremity had remarkable characteristics: it was warty, irregular, fissured, and indented, and had different colours in different parts—purple in one part, grey in another, and perfectly white in the deep indentations or fissures. From the abraded portion exuded, as he before said, this disagreeable glutinous fluid. Seeing that it was a pendulous tumour, that it gave her no pain whatever, and that it, in his opinion, was not of that class of tumours expressed by the term malignant, and fearing if it were allowed to remain in its present situation it might possibly degenerate into that condition known as malignant, he recommended its removal, and Mr. Kane accordingly operated about ten days since with the most favourable results. Dr. McSwiney said he did not undertake to ascribe it to any particular class of tumours, impressed as he was by the knowledge of the fact that the whole question of tumours was at present in a state of great confusion. He left it to the pathologist to determine the actual place in the nomenclature of tumours which it should occupy. Viewing it from a clinical point of view, he recognised in it alone the features of innocency. He regarded it as composed of adult tissue, as a tumour which would not recur, and had not in any way affected the patient's system. He might observe that, in the *Dublin Journal* for 1847, the late Mr. O'Ferrall had reported a case in his "Monograph of Pendulous Tumours" identical in site and in character with the one he (Dr. McSwiney) had now presented. So much was this the case, that the woodcut in Mr. O'Ferrall's paper would answer in all essential particulars to represent the characteristics of the present tumour, of which he now begged leave to present to the Society a photograph fully expressing the lesion. The patient had recovered without any untoward symptom.

Dr. HENRY KENNEDY exhibited

A SPECIMEN OF FATTY DEGENERATION OF THE HEART.

The patient was a woman of 80 years of age, who had been under his observation for four months in the Whitworth Hospital, Drumcondra. Shortly after her admission his attention was caught by the peculiar form of respiration she exhibited; it might be ascribed as high respiration, and used to occur in paroxysms. It was exactly the form to which the late Dr. Graves gave the name of cerebral. It never assumed the precise phases of the respiration to which the name of Cheyne-Stokes' breathing is now given; for while it lasted it was not so regular. But he had no difficulty in arriving at a diagnosis in the present instance. The pulse beat about 66 in the minute, was compressible to a degree, and never showed any irregularity; neither was any morbid sound heard; and this bore out an observation he had made, and which he believed he had established by tabulating more than 250 cases of fatty change of the heart. In these he found that this fatty change and valvular disease rarely co-existed. In fact, for one such case, six at least occurred where, while the heart was fatty, the valves were healthy. In the present instance this point was confirmed; for though the valves were not absolutely healthy they were affected in the very slightest degree, but not so as to affect their functions, or give rise to

any morbid sound. It would be observed that the fatty change in this instance had affected the right side most; but both sides were involved, and to such a degree that a very slight pressure was enough to cause the heart's substance to break down into a pulp. He was indebted to Mr. Elliot, the resident pupil, for making the post-mortem examination.

ARMY MEDICAL REPORTS.

II.

In our former notice of the Army Medical Report for the year 1872, we spoke of the health of the troops serving at home. We now proceed to notice the account given of the health of that part of her Majesty's forces which is stationed in foreign countries.

And, first of all, it seems that in 1872 there were about 4000 men stationed on the rock of Gibraltar, and there were only 21 deaths, showing a most healthy season in that somewhat monotonous sojourn.

In Malta there were about 4,900 troops on an average in 1872, of whom 44 died, so that this was also a very healthy season in Malta. The troops at Malta seem to have had but little venereal contagion during 1872, as the number of 34.4 per 1000 admitted for *syphilis* during the year testifies. Gibraltar had 74 admissions in 1872 for these diseases per 1000 troops.

With respect to the troops quartered in the cold but healthy climate of Canada, it appears that, in 1872, there were only 1,602 troops in that quiet and orderly province. There were less than 5 deaths per 1000 among the troops, which promises fairly to those agricultural emigrants who have recently been attracted in such large numbers to Canada. In Bermuda there were in 1872 about 1,800 men, of whom 13 died, a very low mortality indeed. In the Windward and Leeward Islands, or the West Indies, we see that at Jamaica there were but 354 men, of whom 5 died, one of these of yellow fever, and 3 of phthisis. To those who remember what a graveyard Jamaica used to be, the death-rate of some 14 per 1000 is indeed an amazing stride in army hygiene. It is curious, however, to find that more than 30 per 1000 of the black troops in Jamaica died in the year 1872.

In that pestilential climate, Western Africa, it seems

that the average strength of the black troops serving at Sierra Leone was 207, of whom 9 died, which is at the rate of 43 per 1000. At the stations on the Gold Coast the average strength was 171, of whom 6 died, or 35 per 1000. So that, as usual, these stations seem quite unfit for serving as suitable habitations either for whites or blacks.

Turn we now to the healthy stations of the Cape and St. Helena. In 1872 these two stations contained about 2,500 men, of whom 23 died, including 4 invalids sent to Netley. These deaths are in the ratio of 9.25 per 1000. There seems to have been a good deal of venereal contagion, 157 per 1000 troops, in 1872.

In the Mauritius the health of the troops, 469 in number, was excellent in 1872; namely, only 6 per 1000 died. The admissions for primary and secondary syphilis were in the ratio of 57 per 1000.

The island of Ceylon is usually a very unhealthy station. There died, out of 1000 men, the number of 25 in 1872. The admissions for syphilis were 79 per 1000.

In China, another most unhealthy station, there were 769 men in 1872, of whom 15 died, or about 19.50 per 1000. Urinary diseases were above the average, and considerably more prevalent than during the preceding year. The excess occurred in gonorrhœa and its sequelæ, from which the admissions were in the ratio of 143 per 1000; whilst syphilis caused 69 admissions per 1000.

We next come to the "greatest of the jewels in England's Crown," India, and here we find that the average strength of the European troops serving in the Indian commands in 1872 was 59,248, of whom 1,499 died, 60 on the passage homeward to Netley. This gives the ratio of deaths as 25.30 per 1000, not a very high one for India. As usual, Bengal has the highest death-rate of the three presidencies. In Bengal, out of 36,839 men, 8,733 were admitted into hospital for continued fever, and 13,558 for paroxysmal fever; 588 admissions occurred from malignant cholera, and of these 387 died. There were 3,139 admissions for syphilis. Continued fevers were more prevalent than during the previous year; the ratio of mortality was about the same as before. The increase in the ratio of admissions was caused by the epidemic of dengue, which caused 4,026 admissions into hospital in 1872, but no deaths. Of enteric fever there were 104 admissions and 51 deaths; of cerebro-spinal fevers 21 were admitted, and 6 died.

Malignant cholera was greatly more prevalent in Bengal, and more fatal too, than during the previous year. Only one case (at Allahabad) is shown in the first Quarterly Return of the Command; but in April there were 4 cases and 3 deaths at Benares, and then they continued to extend in a northerly direction, until it invaded the whole of Northern India. The period of the rains was the time at which the epidemic of cholera was severest, and it fell with greatest severity in the Punjab. The corps which suffered most severely was the 37th, at Meer Meer, in which there were 99 admissions and 63 deaths.

In this epidemic generally, the fatality of the disease was unusually great, the proportion of deaths to cases having been 65.8 per 1000. Including all cases among officers, men, women, and children of her Majesty's British Service, there were 856 admissions and 564 deaths.

There were 118 admissions for sun-stroke, of whom 44 died.

Diseases of the urinary system were rather less prevalent. The admissions for gonorrhœa and its sequelæ were 96 per 1000. There were 85 admissions per 1000 troops for syphilis. Boils and ulcers formed the chief kinds of skin diseases for which admission into hospital was sought for in the Bengal Presidency.

"The real reason (says Inspector-General Beatson) why regiments on arrival in this country suffer so much I believe to be that newly-arrived regiments are, as a rule, more largely composed (in order to make up their number prior to embarkation) of weakly ungrown lads; secondly, there is doubtless a great deal of inexperience of Indian ways and requirements on the part of the new arrivals; and, thirdly, there is the fact, quite apart from the acclimatization theory, that new arrivals are for the first year or two more liable to attacks of acute tropical disease than they are at a later period: this results, in some degree, but not altogether, from the fact that at first they do not realise that they cannot do in India as they have been accustomed to do at home."

The remedies he proposes are, that young men should not come to India earlier than 21 or 22 years old, and should pass their first two years of service among the hills, if possible. The proposed system would involve at least one-third of the European forces being on the hills, and he cannot see anything against this.

In the Madras Presidency cholera did not prevail epidemically; and enteric fever caused only 79 admissions into hospital and 26 deaths. There were 92 admissions per 1000 into hospital from syphilis. Under the heading *poisons*, it seems that all the admissions were from delirium tremens. In Burmah, of 6 admissions from this cause, there were 2 deaths.

During the year 1872 the dry-earth system of latrines was made use of in the Madras Command. Mutton is reported to be scarce in that province, and beef forms the chief meat ration, except for two days in the month, when salt pork and beef, with pickles, are issued, and are greatly relished by the men. Mutton is issued to the sick in hospital every alternate day.

In the Bombay Presidency there were 42 admissions from malignant cholera, with the result of 33 deaths. In the case of syphilis, there was a great reduction from the numbers of 1871; that is, there were 70 admissions per 1000 of strength from the disease in 1872.

There is no country but ours the perusal of the yearly Army Medical Report of which can afford anything like the interest obtainable from the Blue-Book we have just been rapidly skimming over. It is quite amazing to think over what a wide extent of our planet the troops of her Majesty are scattered. Nor can we imagine any better method of obtaining a correct idea of the effect of climate upon health than can be gleaned by the careful student who diligently strives to master the details of this important Report. In a future article we hope to be able to refer to some of the excellent essays contained in the Appendix, which forms about one-half of the bulk of the volume.

THE ACTION OF DRUGS.

IX.

WE have now to review the report of the Committee as to the antagonism between extract of Calabar bean and strychnine, a subject which has already been investigated by Nunneley, Vée, and Eben. Watson, whose inquiries prove that the paralyzing effects produced by the extract of Calabar bean modify to a considerable extent the powerful tetanic convulsions caused by strychnia; but the above experimenters have failed to prove that recovery may take place after a fatal dose either of the one or of the other drug. Such being the case, the Committee proceeded in their usual careful and methodical manner, to test this question, and once more chose rabbits as the subjects, because the minimum fatal dose of each substance in these animals had already been ascertained. In the first place, they chose twelve rabbits of nearly the same weight, and introduced into each a minimum fatal dose of strychnia; then, having allowed four minutes to elapse, they introduced into the same animals the minimum fatal dose of extract of Calabar bean. With another set of twelve rabbits they reversed the process. The results obtained from these experiments are thus summed up by Professor Bennett:—

There was no instance of recovery except in Experiment 560; but in this instance the dose of strychnia was not fatal, 1-80th of a grain, as the animal survived after the same dose when administered eight days afterwards.

It will be seen from Table 63 that not only was there no instance of recovery from a fatal dose of strychnia or of extract of Calabar bean, but that death ensued after the introduction of even non-fatal doses of both substances. It appeared, during the progress of these experiments, that the animal was more likely to recover if subjected to the action of one or other of the substances alone, than when both were introduced. At the same time, the character of the symptoms produced by the action of either the one or the other substance is considerably modified by the presence of the presumed antagonist. Thus, the convulsions caused by the action of strychnia on the spinal cord are not so violent, and have not so much of the character of tetanus, when modified by the action of extract of Calabar bean. On the other hand, the prostration and profuse secretion from the air-passages produced by the influence of extract of Calabar bean are not so great when the animal is at the same time subjected to the action of strychnia. But I have had no example of recovery from a fatal dose of either drug. On the contrary, the advent of death was accelerated. Strychnia and extract of Calabar bean, therefore, are not antagonists in the sense that the administration of the one can save life after the administration of a fatal dose of the other; but they may be considered as antagonists in the sense that the action of the one modifies the symptoms of the other. The extent of the action is not at all comparable to the action of hydrate of chloral and strychnia.

Thus it is evident that no antagonism, in the true sense of the word, exists between these two drugs, at least, in the doses used in the experiments recorded in Tables 72, 73. Whether the result would have been different if smaller doses of strychnia had been used to antagonise fatal doses of extract of Calabar bean, and *vice versa*, it is difficult to say; but we must remember that the experimenters have placed on record the (at first sight) curious facts that, while a dose closely approximating to the minimum fatal dose of chloral is necessary to antagonise a minimum fatal dose of strychnia, yet a fatal dose of extract of Calabar bean is successfully antagonised by a dose of sulphate of atropia,

which, when given alone, is insufficient to produce any visible physiological effect. If our readers will refer to the *British Medical Journal* of Oct. 3 they will observe that Professor Bennett states the minimum fatal dose of chloral to be about 20 grains, in rabbits, and that of strychnia to be 1-96th of a grain; and he administered to a rabbit 15 grains of the one drug and 1-96th of the other, and the animal recovered; then, upon referring to the same journal of Oct. 10th the statement will be found that the minimum fatal dose (for a rabbit) of sulphate of atropia is about 20 to 21 grains, and of extract of Calabar bean, $\frac{2}{3}$ of a grain, but that it is only necessary to administer the exceedingly small dose of $\frac{2}{3}$ of a grain of atropia to successfully antagonise the fatal dose of extract of Calabar bean. We have already commented at length on this point (*vide* MEDICAL PRESS, Dec. 9th), and only call attention to it again as we consider that, bearing this interesting fact in mind, the experimenters might have endeavoured to ascertain if the antagonistic power of strychnia to extract of Calabar bean was not greater in the smaller than in the larger dose; and it is not at all improbable that they might have found such to be the case.

The experiments recorded in Tables 72, 73, however, serve to prove that, although a rabbit may recover from $\frac{2}{3}$ of a grain of extract of Calabar bean given alone, yet, it is extremely improbable that it will recover from even 1-3rd of a grain of that drug if 1-120th of a grain of strychnia be administered at the same time—in fact, death will be hastened. As establishing this point these experiments are valuable.

The antagonism between bromal hydrate and atropine is next a subject of investigation, and the inquiry was carried out by Dr. McKendrick, as regards the physiological action of bromal hydrate; and he arrived at the following conclusions:—

1. Bromal hydrate is a more active substance physiologically than chloral hydrate. A rabbit weighing 4 lbs. requires about twenty grains of chloral hydrate to cause death, whereas four or five grains of bromal hydrate are quite sufficient to kill.

2. Chloral hydrate produces, in small doses, or soon after a large dose, marked hyperæsthesia, followed by anaesthesia. Bromal hydrate never produces hyperæsthesia, and anaesthesia only when the animal is in such a state of coma that there is no hope of its recovery.

3. Chloral hydrate does not usually produce great contraction of the pupil. Bromal hydrate always does.

4. Chloral hydrate acts chiefly on the cerebral hemispheres; and never, so far as we know, has been known to cause convulsions. Bromal hydrate acts less vigorously on the hemispheres, and more on the ganglia at the base of the brain and on the spinal cord, the animal frequently dying in a state of opisthotonos.

5. After death from chloral hydrate, fluid is rarely found in the shut sacs of the body. In the case of death from bromal hydrate, fluid is almost invariably found.

6. Chloral hydrate does not usually stimulate the salivary glands to the same extent as bromal hydrate does; but in this instance there are exceptional cases in which chloral hydrate causes excessive secretion of saliva in animals.

In reference to the action of iodoform, the report contains the following highly interesting remarks:—

There is a difficulty in the way of obtaining knowledge of the action of iodoform, on account of its want of solubility in any menstruum suitable for subcutaneous injection. It is scarcely soluble in water, acids, or aqueous alkalies,

but it is readily soluble in alcohol, ether, and oils, both fixed and volatile. A number of experiments were performed with a solution consisting of one grain of iodoform in five grains of alcohol and fifteen grains of water. The effects were very similar to those produced by chloral, with these exceptions. (1) There was no period of hyperæsthesia. (2) There appeared to be a feeling of irritation of the nostrils, as the animals rubbed the nose frequently with the fore-paws. (3) Ten grains subcutaneously injected into rabbits of 3½ lbs. weight produced profound sleep for a period of four hours. Twelve grains killed rabbits of the same weight in 2½ hours. The fatal dose thus appears to be smaller than in the case of chloral, and larger than in the case of bromal. (4) There were no convulsions. (5) The pupils were only slightly contracted. (6) There was no fluid in the cavities of the body after death from iodoform, while it was always found after death caused by bromal hydrate, and frequently in cases of poisoning by chloral hydrate.

A series of experiments are next conducted to determine the minimum fatal dose of bromal hydrate, which is found to be, for a rabbit weighing 3 lbs. 8 ozs. to 3 lbs. 11 ozs., about 4 grains; and then the main object of the inquiry—viz., to ascertain whether or not life could be saved from an otherwise fatal dose of bromal hydrate by the subsequent action of *small doses* (italics ours) of atropine is proceeded with, and the experiments recorded in Table 75 are highly important and interesting, and we quote the remarks of Professor Bennett upon the results obtained, as they are highly suggestive to anyone who has carefully perused the report now under consideration, and who perceives the growing importance of recognising the different effects produced by large and small doses of the same drug. Experiments 606, 607, 608, 609 showed that the small dose of 1 to 1½ grains of atropia was sufficient to antagonise the fatal dose of 4 grains of bromal hydrate. The Professor thus concludes this portion of the report:—

This is a clear example of physiological antagonism; and it is one of the few in which an explanation can be offered. Death from the effects of a minimum fatal dose of bromal hydrate is due almost invariably to the accumulation of saliva in the mouth and mucus in the air-passages. This accumulation is frequently so excessive as to suffocate the animal and cause death by asphyxia. The convulsions which usually occur immediately before death in cases of poisoning by bromal hydrate are due to asphyxia or the action of venous blood on the nerve-centres. Atropine arrests this secretion, partly by diminishing the action of the salivary glands, and also by causing contraction of the blood-vessels in every part of the body. This contraction diminishes the supply of blood to all the serous and mucous surfaces, and consequently there is less secretion from these surfaces. It is evident, therefore, that small doses of atropine favour recovery in cases of poisoning by bromal hydrate.

When, however, the process was reversed, and small doses of bromal hydrate (such as ½ to 3 grains) were given after doses of from 3 to 4 grains of atropine, it was found that all the animals died; and while the doses of the drugs were in the proportions of 1½ to 2½ grains of bromal hydrate to 3½ or 4 grains of atropine, the animal survived for a longer period than when the doses were beyond these limits; hence the experimenters concluded, although small doses of atropine may save life, after fatal doses of bromal hydrate the converse does not hold good.

MEDICAL FEES AND MEDICAL WITNESSES.

In the course of a case tried in the Court of Common

Pleas last week, a point of law was raised of some importance to the profession. A gentleman, overturned in his brougham by the negligence of the driver of a tramway car, received a severe concussion of the spine, and brought his action to recover damages. His ordinary family medical man, who it appeared had attended him for eighteen years, lives on the south side of the Thames, while he resides in the north, and since his removal he has not demurred to pay him what might be considered a very moderate fee for his attendance, namely, 7s. 6d. per visit. The presiding judge, in directing the jury as to assigning damages, thought it right to challenge this item, because he elicited from the witness that his charge to patients living in his own immediate neighbourhood was 3s. 6d. The judge thereupon said it was not right to make the Tramway Company pay more than his ordinary fee, and that the plaintiff should himself pay the extra charge; since his having called in a gentleman living a long distance, rather than one in his immediate neighbourhood, must be regarded as a luxury rather than as a necessity, although the plaintiff's life might really have been saved by one better acquainted with his constitution, health, &c., which we know are matters of much importance in cases of far less gravity than concussion of the spine. No objection to the charge was taken by the counsel for the defendants, and whether the jury adopted the views of the judge, of course, we are unable to say, but for the sake of fair and honest dealing we trust they did not. It is to be hoped twelve jurymen will not be found to endorse and adopt views which, to say the least, are niggardly, and which certainly bear very unfairly upon the hard-working members of our profession. It does appear somewhat arbitrary on the part of the judge to maintain that a general practitioner is not fairly entitled to make a higher charge for a visit occupying an hour and a half of his time than for one occupying a third of an hour.

Other points of importance were raised by the plaintiff's counsel as to whether a court of law is a fit place to air crotchets in, and also as to the questionable position often assumed by members of the profession, who, when they appear on behalf of companies, do so rather in the character of advocates than of medical men. In this instance a physician stepped into the witness-box to say he had seen and examined the plaintiff some seven months after the accident, and that in his opinion paralysis well marked, and in which no question of its origin existed, was due, not to the accident, but to a *syphilitic taint*. The only ground for the surmise was that six years before the plaintiff had suffered from some affection of the skin of the most ordinary character, but which he thought might be a specific. We fear the learned counsel was not far wrong when he said it appeared to him that to become medical referee to a company was a position likely to produce a very demoralising effect upon some men.

THE IRISH COLLEGE OF PHYSICIANS.

As we have felt ourselves bound to give the fullest fair play alike to the College and its Dissentients, we have published to-day all the relevant portions of the "Rejoinder," which will, we trust, be the last contribution of the com-

batants to the official literature of the controversy. The paper war has, in fact, rather outlived the interest of the profession, and as the entire dispute lies within the compass of very few words, we imagine that each reader is sufficiently informed upon it, and has formed something like a definite conclusion. For ourselves, we may say that we have had no occasion to recede from the opinion which we formed on first consideration of the matter—an opinion which, we venture to believe, will be shared by the great majority of the profession in Ireland.

In the first place, as regards the ballot, we warmly approve the course taken by the Dissentients, and entirely disagree with the views of the Fellows. We look upon the ballot as no legal or fitting test for admission to the Fellowship; we dispute the right of any number of gentlemen in possession of a privilege to exclude *proprio motu* from a right which they should legally enjoy persons who are presumed to be eligible in point of competency. We deny the analogy of the precedents which have been quoted in favour of the ballot, and hold that even if applicable instances could be found in other medical corporations, it would be highly inexpedient to assimilate the College to such bodies in this respect. We believe that the ballot has never been actually used by the Fellows for the purpose of religious or political ostracism, but we object to its perpetuation, if for no other reason, because it might at any time be so used.

While thus unconditionally declaring against the election to the Fellowship by ballot, we are well aware that the wholesale admission of Fellows which the Dissentients advocate is entirely inconsistent with the efficient administration of the College as at present constituted, and we think that the Government, in considering the proposed modifications of the Charter, will find it necessary to vest executive management in the hands of a Council before they can grant the prayer of the Dissentients. We have shown that the Dissentients have made no effort to make their amendments practicable, but, on the contrary, have resisted proposals made with this object, and they are open, therefore, to the charge of desiring to effect the ingress of their party to the College without regard to its administrative efficiency.

As regards the propriety of establishing a New Order of Members, we look upon the proposal as a means of permitting access of Licentiates to the College, and yet excluding them from the sacred conclave of the Fellows. We doubt that the disabilities under which Licentiates are said to labour in seeking appointments in England are sufficiently numerous or important to make necessary the creation of the new order, and if there were a Fellowship freely accessible to those who proved competency, and a Council invested with the administration of the College, we fail to see what would be gained by calling the Licentiates members. At the same time we must say that the Dissentients have entirely failed to prove their allegation that the new order was simply a method of imposing a tax on the Licentiates, a statement for which, as yet, there would appear to be not a tittle of foundation.

Our only other observation upon the matter is an expression of regret that the controversy has not been conducted with much dignity or temper by the Dissentients. "Puerile," "childish," "mockeries," and such like expletives are not the suitable language of public documents; nor are the title "fool" and the attributes

of "falsehood and stupidity" suitable to gentlemen engaged in a debate on a serious professional matter. Neither the Chief Secretary nor the public will think the better of statements garnished with such phrases, nor of the side which makes use of them. We have had much of the *fortiter in re*, but too little of the *suaviter in modo*.

Notes on Current Topics.

Dublin Sanitary Salaries.

THE Dublin Corporation has allowed its ire free effervescence in a recent debate upon the action of the Irish Local Government Board who increased by a sealed order the salaries of the sanitary medical officers of Dublin. While obliged to admit their entire impotency to resist the Local Government Board, the Public Health Committee is very irate at the defeat of its attempt to nullify the operation of the Public Health Act. The Chairman of the Committee complained of the way in which the Local Government had acted with regard to the salaries of the medical officers under the Sanitary Act. The sanitary duties of these gentlemen, he said, were *absolutely nothing at all, because the sanitary police did the work*. Just so! Parliament and the Committee of the House of Commons thought it wise to confide sanitary inspection to the medical officers; but the Public Health Committee could not forego the gratification of a job. Their *protégés*—a number of ex-policemen—had been promised nice places and good salaries and the Committee could not disappoint them. They, therefore, appointed a number of such officers at salaries from £160 downwards, and having thus, without care or conscience, voted away the money of the citizens to unnecessary officials, they wished to deprive the sanitary medical officers of their salaries in order to recoup some part of this indefensible extravagance. The Chairman thought that "if the Government knew that the Corporation had already the most complete sanitary organisation in Ireland, or perhaps in England, they would not have approved of this procedure." The boldness of assertion of the worthy Chairman is admirable. It is amusing to read such a phrase when one knows that the Dublin Public Health Committee is probably the very least efficient and most obstructive sanitary organisation in the three kingdoms. If the action of the Legislature in placing the supreme control of sanitary matters in the hands of the Local Government Board needed justification, the Dublin Corporation has made abundantly clear the wisdom of having done so.

Supposed Transmission of Fever by Milk.

At a recent meeting of the Dundee Police Commission, the medical officer, in reporting in regard to an outbreak of typhoid fever in the east end of the town, referred to the probability of infection having been generated from milk. All the houses in which the fever had occurred were supplied with milk from a dairy in the neighbourhood. Since August four persons who live in the dairy had been suffering from fever. The bed-room occupied by them during their illness was on the ground floor, and

contained two boxed-in beds. The room measured 1,384 cubic feet. Opening off the apartment was the milk-house, which also communicated with the kitchen by a door opposite to the first. The doctor, however, stated that whatever connection the milk supply might have had with the present outbreak of fever, he was forced to the conclusion that the proximity of the milk-house had no direct influence in communicating disease. We may still doubt, however, whether the close proximity of the milk-house to the beds in which the patients were lying, combined with the facts that the persons attending on the patients also handled the milk, may not have been the cause of its becoming saturated with the germs of the disease, which by its means was conveyed to those who used it afterwards as food.

Medical Men in the Commission of the Peace.

WE are gratified to observe that the Irish Government have seen the propriety of drawing back from the prohibition which they had put upon Irish medical men holding the commission of the peace, upon which we commented last week and on a former occasion. On the recommendation of Colonel Peel Dawson, the Lieutenant of the county, the Lord Chancellor has appointed Dr. James C. L. Carson and Dr. Robert Sharpe, both of Coleraine, to be magistrates for the county of Londonderry.

We may thank, we fancy, the exit of the Lords Commissioners, who held temporary custody of the great seal, and the access to power of the new Lord Chancellor for this change of policy, which can hardly be grateful to Sir M. H. Beach. As the former veto was against the whole profession, and not against any individual, we would advise the medical men who were ousted by it to cause their names to be again submitted for approval.

A Specimen of Nomenclature.

OUR chemical readers will doubtless be pleased to learn that a series of acids have been investigated. One is orthoamidotoluenesulphonic acid; and another diazorthoamidoparatoluenesulphonic acid. The action of tin and hydrochloric acid on nitro-bromacetanilide gives rise to the hydrochloride of *ethenylbromophenylenediamine*.

Medical Officers of the Navy.

THE following regulations in reference to the position of the medical officers of the navy, submitted by the Lords Commissioners of the Admiralty, were approved of by her Majesty at the meeting of the Privy Council held on Thursday:—1. That surgeons on entry shall have the same relative rank as paymasters, chief engineers, and naval instructors, namely, shall rank with lieutenants under eight years' seniority, and shall have uniform corresponding to such relative rank. 2. That staff surgeons shall be denominated "fleet surgeons," and staff surgeons, 2nd class, simply staff surgeons, the distinction in rank between these two grades to be denoted by a small difference in the uniform. 3. That inspectors general shall be compulsorily retired at the age of 60, on £2 per day, provided they shall have completed the period of service now required to entitle them to the maximum half-pay of their rank. 4. That deputy inspectors general shall be compulsorily

retired at 60, if in the first six of their rank, at 33s. per day, others at 30s. per day, provided that they shall have completed the period of service now required to entitle them to the maximum half-pay of their rank. 5. That fleet surgeons and staff surgeons shall be placed on the same scale of retirement as chaplains and naval instructors, secretaries, and paymasters, that is, the maximum to be £450 per year instead of £400. 6. That any fleet surgeon shall have the option of retiring after 20 years' full pay service in all ranks at 15s. per day, and after 25 years' service at 21s., subject in each case to our approval, but that of those now on the list not more than ten shall retire under this clause in each year (the officers having the option according to seniority), unless we should approve (with the consent of the Lords Commissioners of her Majesty's Treasury) of a larger number so retiring. 7. That of the medical officers to be hereafter entered all shall have the option of so retiring, subject to the approval of the Lords Commissioners of the Admiralty in each case.

Medical Affairs in the New Parliament.

IN the speech from the Throne on the opening of Parliament on Friday last, it was mentioned that bills would be laid before the House for facilitating the improvement of the dwellings of the working classes in large towns; for the consolidation and amendment of the sanitary laws; and for the prevention of the pollution of rivers.

Notices of motion were also given of the following:—

MR. SCLATER-BOOTH.—On Thursday, a bill to consolidate and amend the acts relating to public health in England. On Friday, a bill to repeal the Adulteration of Food Act, and to make better provision for the sale of food and drugs.

SIR H. JOHNSTONE.—On Monday, a bill to repeal the Contagious Diseases Acts.

MR. BROOKS.—On an early day, a bill to regulate the office of coroner in Ireland.

MR. COWPER-TEMPLE.—On Monday, a bill to remove doubts as to the admission of women to degrees in the universities of Scotland.

The Spread of Small-pox by Inoculation in the West of Ireland.

THE *Sligo Independent* regrets to hear that a most virulent type of small-pox has become a prevailing epidemic in the neighbourhood. So extensively has it spread that it was deemed advisable by the magistrates to discontinue holding petty sessions courts in the town for the present. It believes the disease was imported into the locality by inoculating quacks from Mayo, who are considered benefactors by the ignorant peasantry of this benighted district. The constabulary, we believe, are using every exertion to try and arrest the originators of this dire disease, and it suggests that the Roman Catholic clergy should use their influence to prevent the people being misled and made dupes of by those quacks who are spreading a pestilence.

MR. PRESCOTT HEWETT has resigned his post as Surgeon to St. George's Hospital.

Jaborandi.

Dr. SYDNEY RINGER says that the dose of jaborandi for an adult is from 60 to 90 grains infused in boiling water. In the course of twenty observations made on eighteen adults, the perspiration in every case but two caused by drinking this effusion was most profuse, commencing in about ten minutes. Salivation was also profuse in many instances. The pulse generally rose. The temperature of the body fell during the sweating. In some cases it was found that the introduction of an extract dissolved in glycerine into the eye caused contraction of the pupil. Probably jaborandi paralyses the sympathetic nerve. Its effects do not seem to be so well marked on children as on adults.

Brighton Amenities.

We all delight in Brighton. It is our holiday when we have a day to spare and the sense to profit by it at the sea-side. For some time that magnificent city has been singularly free from zymotic disease; but if the corporation goes on depositing filth on the shore, as it is now doing, we shall not be long in hearing of some outbreak of typhoid fever or other disease caused by decaying animal and vegetable matters.

Garibaldi as a Sanitarian.

EVERYONE now-a-days seems to have got tired of politics for a season. The cry now is—let us make the world healthier, and our towns cleaner and less miserable. This is as it should be. Garibaldi was long a gallant hero in the cause of freedom from priestly tyranny and governmental incapacity; and if he now finds the enemy of the whole race to be in reality poverty, with its concomitants filth and over-crowding, we may hope that he will not be easily daunted in attacking them. Italy will give him plenty to keep his energies alive. It is beautiful, but filthy.

Professorship of Chemistry in Dublin University.

At a meeting of the Board on Saturday, Dr. Reynolds, Professor of Chemistry in the College of Surgeons, and to the Dublin Society, was elected to this chair. The emoluments amount to about £800. There were ten candidates, only three of whom the Board wished to see. These were Dr. Reynolds, a chemist of great eminence, Dr. Apjohn, son of the late professor, who obtained the gold medal in experimental physics, and is now Professor in Chins College, and Dr. Mallett, son of an eminent engineer, and who also obtained the gold medal.

Forewarnings of Medical Legislation.

HER MAJESTY'S speech gives assurance that the sanitary session of last year will be followed by further important legislation in the same direction during the present term. The pollution of rivers, the dwellings of the working classes, are to have special attention, and the consolidation of sanitary law is to be followed up. From private members we have the usual enunciations of intentions, which may probably never be carried into effect, and certainly will produce no useful fruit. Sir H. Johnstone has tabled his own special craze on the Contagious Diseases

Act; Mr. Cowper-Temple has also brought in his Bill to throw open the Edinburgh University to the ingress of women, and Mr. Brooks is to reintroduce a Coroner's (Ireland) Bill—we presume the same as Sir John Gray, Mr. Vance, and Mr. McCarthy Downing had charge of last year. Lastly, Mr. Sclater-Booth has promised in the current week a Public Health (England) Amendment Bill, and a Bill to repeal the Adulteration Act, in the latter of which we most heartily hope he will be defeated.

We hear that the Medical Reform Bill of the British Medical Association is ready, and may be looked for as soon as Mr. Headlam or any other member can be got to "father" it.

THE election of an examiner in midwifery in the room of Dr. Croyn, appointed Professor, and also of a councillor in the room of the late Mr. Adams took place in the Irish College of Surgeons on Thursday last. There was no contest for the vacant councillors seat, Dr. Corley having withdrawn his name, and Mr. Henry Gray Croly, Senior-Surgeon to the City of Dublin Hospital was elected.

For the examinership two candidates presented themselves, Dr. Croly, of Rathfarnham, and Dr. Shannon. Dr. Croly was elected, and thus returns to the seat which he occupied many years ago on the Midwifery Court of the College.

It has been stated editorially by the *Irish Times* that Professor Haughton is engaged on a work on the art and science of hanging, *not* pictures, but men, which, considering the practical comment on his former calculations afforded by recent experience, indicates great courage on his part. Our contemporary records that an interesting relic has been confided to the care of the learned Professor, being nothing less than the rope which hanged Montgomery, which was secured and preserved by Dr. Murray, as *Examiner to the College of Surgeons*. We need hardly say that Dr. Murray did not attend the execution-deputed or in any way representing the College.

DR. FAYRER has been elected Corresponding Member of the Academy of Natural Sciences of Philadelphia.

A FORTNIGHT since we announced that Dr. E. M. Grace, the renowned cricketer, was a candidate for the office of Coroner for the Western Division of Gloucestershire. We have now the pleasure to announce his unopposed election.

THE library of the late Dr. Lankester will be brought under the hammer of Messrs. Puttick and Simpson, in Leicester Square, on Tuesday next and two following days. We understand that it is both an extensive and valuable collection.

SIR W. JENNER will preside at the next meeting of the Clinical Society on Friday. The meeting will begin at 8.30 with the delivery of Sir William's Inaugural Address.

At a full meeting of the Metropolitan Asylums Board, on Saturday, the Committee reported that, after having

visited the proposed substitute sites for the hospital for contagious diseases at Hampstead, they were of opinion that they were neither so convenient nor in any way so appropriate as the original one. The Board thereupon decided that their entire body should visit the three sites on Thursday, before finally deciding upon which to adopt.

MR. HOLLOWAY, of pill and ointment notoriety, is reported to have purchased the Mount Lee Estate at Egham, for the purpose of establishing a college for women, which, when finished, will accommodate 400 students. The ground cost £25,000. The building is to cost £175,000.

THE IRISH COLLEGE OF PHYSICIANS.

REJOINDER OF THE DISSIDENTS TO THE LETTER OF THE COLLEGE TO SIR M. HICKS BEACH, BART., M.P.

[*Abstract.*]

To the Chief Secretary for Ireland.

SIR,—As the Charter Memorial Committee have numbered separately each paragraph of their Report of the 22nd December, we have, for the sake of clearness, adopted the same course.

PARAGRAPH 1. "That the President and Fellows, in seeking permission to use the ballot in elections, are not seeking any unreasonable or unprecedented powers, as a perusal of the dissent might lead one to suppose, but are merely asking for a privilege which is already enjoyed by nearly all the medical corporations and chartered societies in Great Britain and Ireland."

Rejoinder.—This is a vague, unsatisfactory statement, inasmuch as it does not specify the medical corporations and universities by which the ballot is possessed. We specify four in Dublin—one the Royal College of Surgeons, within the profession, into which entrance into Fellowship is procured by examination, and the Fellowships are unlimited in number. The Fellows of that College now number nearly 400, while the College of Physicians numbers, as stated in the Report, only 45 efficient Fellows. (*Vide par. 3 of Report.*) The other, outside the profession, the benchers, who stand in relation to barristers much in the same position as the College of Physicians stands to physicians. They are self-elected, but do not vote by ballot. The Council of the University of Dublin is not elected by ballot; nor does the Convocation of the Queen's University in Ireland elect to the Senate by ballot.

PARAGRAPH 2. "That the College, in seeking for the use of the ballot in voting, accepts the principle that the majority of votes shall decide the result."

Rejoinder.—The College deserve no credit for this, for they did not surrender the monstrous injustice of their bye-law—that one black bean in five should exclude—until the Visitors had pronounced the bye-law illegal. It is not to be forgotten that, even when the majority decided the election, two Roman Catholics of the highest position were rejected—gentlemen whom the College, with tardy justice, have since elected as Fellows.

PARAGRAPH 3. "That the number of Fellows resident in Dublin and its vicinity, and attending, with more or less regularity, the meetings of the College, is 45, of whom only five have dissented from the provisions of the proposed Charter."

Rejoinder.—This admission is, it appears to us, a sufficient condemnation of the system pursued in the College, that while, at the end of 90 years, the Royal College of Surgeons numbers nearly 400 Fellows, in our own College, after 200 years, the Fellows barely exceed 50 in number, and of these the average attendance is only 15. It does not follow, as the Memorial Committee would imply, that only five have dissented, and that all the remainder assent to the proposed Charter.

PARAGRAPH 4. "That, during the forty years, when the practice of voting by ballot prevailed, no complaint to the Visitors was ever made against the practice."

Rejoinder.—The only surprise is, that there ever was a

complaint to the Visitors, when it is known that the visitation in 1870 cost upwards of £400, an expense sufficient to deter any rejected candidate from appealing, who in an appeal would have to contend with his private resources against a corporation; nor, perhaps, would there have been the appeal to the visitors in 1870 were it not that the College had superadded to election by ballot the monstrous bye-law of one in five excluding, which virtually put the election of a Fellow into the hands and private arrangements of about six voters.

PARAGRAPH 8. "That while freely admitting the assertion of the Dissenters, that the duty of co-opting new Fellows into the College is a trust, for the exercise of which the existing Fellows should be responsible to professional opinion, it is at the same time one in which they should be protected from the undue influence which could so easily be exercised upon them by candidates, however undeserving of the Fellowship, who were supported by a powerful political, religious, or social party."

Rejoinder.—This statement freely admits "the assertion of the dissenters that the duty of co-opting new Fellows is a trust for the exercise of which the existing Fellows should be responsible."

This appears to us to grant our whole case. The Fellows cannot be held responsible unless it is known how they voted; and as to the necessity which it is asserted should exist to protect Fellows "from the undue influence which could so easily be exercised upon them by candidates, however undeserving of the Fellowship, who were supported by a powerful political, religious, or social party," we feel thoroughly ashamed of this defence of the ballot; but if the majority of the Fellows are so cowardly and mean-spirited as they would here represent themselves to be, let them adopt the principle of the College of Surgeons, and admit to Fellowship by examination in open court.

PARAGRAPH 10. "That one of the effects of the operation of open voting would be to deter many of the most valuable Members of the College from taking an active part in the management of its affairs."

Rejoinder.—This is a gratuitous assumption of what is to come: open voting does not deter voters in other chartered corporations from attending, nor does it appear that during 140 years when open voting was the rule, it deterred Fellows from attending, much less that it deterred the "most valuable members of the College."

PARAGRAPH 12. "As the Dissenters appear to make it an objection that in the King and Queen's College of Physicians there are now no more than 55 Fellows, the President and Fellows find it necessary to reply that in the University of London—a great and most important institution—the number of Fellows is only 36, and that in the other Colleges of Physicians, Colleges of Surgeons, Glasgow Faculty, and in all the incorporated scientific and literary societies, in which the number of Fellows or Members is unlimited, there is a Council or other governing body of a small precisely defined number, usually 21; but in the London College of Physicians, but 18; and in the Edinburgh College of Physicians, only 7."

Rejoinder.—There is no analogy whatever between the University of London and the King and Queen's College of Physicians as to the number of Fellows and mode of election. In the College of Physicians the number that may be elected is unlimited, and they have the power of election to Fellowships in their own hands. In the University of London, the number of Fellows is limited by the Crown to 36, and they enjoy no power of self-election.

PARAGRAPHS 13 and 14.

Rejoinder.—The reply to the disclaimer in Paragraph 13, "of any intention to use the proposed vote by ballot to the disadvantage of candidates who may happen to differ from them in religion or politics," is abundantly answered by Paragraph 14 in their own words, "that of the five candidates who were rejected under the bye-law since declared illegal, four were Roman Catholics, and one was a Protestant, but there was this difference between them, every one of the Roman Catholics would have been admitted had a simple majority, as is now sought for, carried the election."

We ask, who was it that passed this illegal bye-law? The College itself; and although the College admits it was illegal, it has never taken a step to repair the injustice inflicted (as they admit) upon the four candidates.

PARAGRAPH 16. "That the bye-law which the Visitors have pronounced illegal was framed for the sole purpose of

preventing the indiscriminate admission to the Fellowship of Non-Graduate Licentiates—a measure which the College considered the Act 25 Vict., ch. 15, gave them full power to guard against, since in its concluding paragraph it specially enacts that the Fellows shall admit Licentiates who are not Graduates under such limitations as to them may seem fit."

Rejoinder.—With regard to the bye-law mentioned here, viz., that one-fifth was to exclude, the visitors pronounced it illegal, and that is enough. There could never be "indiscriminate admission," for a majority would have excluded any unfit candidate. When the same argument was put forward by counsel before the visitors, the ironical observation of the Chief Justice of the Common Pleas was: "If they may do that, they may do anything they like."

PARAGRAPH 17. "That the College desires to have the power to create an Order of Members similar to that which is possessed by the Royal Colleges of Physicians of London and Edinburgh, inasmuch as there are numerous valuable medical appointments in England which can only be held by Fellows or Members of a College of Physicians. From these the Licentiates of this College are necessarily excluded, and it is in consequence of remonstrances addressed to the College by various Licentiates who have suffered from this disability, that this power is now sought, whereas not a single Licentiate has objected to the creation of the new order."

Rejoinder.—There is not a single instance given of a remonstrance to the College in regard to any public appointment. Such an exclusion might have existed before 1858, the date of the passing of the Medical Act; but the Act of 1858 establishes reciprocity of right to practise in every part of the United Kingdom for every duly qualified practitioner registered under that Act; and any objection founded on the assumption that a candidate had not a licence from some particular college was illegal.

It is obvious that Licentiates are equally eligible with all other Licentiates, Members, and Graduates to public appointments in England; and that it is an unfounded pretence to put forward as a reason, for seeking a new order, that there are "numerous valuable medical appointments in England which can only be held by Fellows or Members of a College of Physicians."

The New Order proposed to be established would be merely a toll-bar, at which every Licentiate aspiring to a Fellowship would be obliged to submit to a farther tax, for it would be soon intimated that at election for Fellowship it would be in vain for any but a Member to offer himself.

With regard to the last part of Paragraph 17, that not a single Licentiate has objected to the new order, there is good reason to doubt this; but even were it so, it is to be recollected that the College has, up to the present, conducted its proceedings, as far as it could, in secrecy, that it never laid the proposed Charter before the Licentiates; and that even the proposed Charter was forwarded to the Lord Lieutenant on 4th August, 1874, without its being laid before the Fellows, and that it was only in consequence of a letter received, from Sir M. H. Beach on the 6th November, 1874, inquiring if there were any dissentients, that the Charter was laid on the table of the College, for the instruction and consideration of the Fellows.

NOTICES TO CORRESPONDENTS.

MR. HESLIAGE BUCKLEY is thanked for his complimentary letter.

DR. CARDIFF's letter shall have attention.

M.—A review of the book is in type, and will appear in our next.

JUN D'ESPRI.—Withcisms at the expense of the profession are not uncommon, therefore we do not see why its members should not enjoy the jokes as much as those who make them. Here are two of the latest we have heard:—

"Madame," said a cross-tempered physician to a patient, "if women were admitted to paradise their tongues would make it a purgatory." "And some physicians, if allowed to practise there," replied the lady, "would soon make it a desert."

"Now, then," said a physician, cheerily to a patient, "you have got along far enough to indulge in a little animal food, and—" "No you don't, doctor," interrupted the patient; "I've suffered enough on your groel and slops, and I'd starve sooner than begin on hay and oats."

A QUERY

To the Editor of the MEDICAL PRESS AND CIRCULAR.

DEAR SIR.—A short time ago a stout healthy man was attacked with what I can call nothing else than "neuralgia of the bronchial plexus," commencing down to the fingers, and causing a sensation of numbness, besides a most excruciating pain all over the arm. I have tried every remedy I could think of, and besides what several medical men prescribed, but all to no purpose. The pain still continues, though most improved sight. Galvanism gave most relief for a time, but does no

good now. There is nothing whatever the matter with his health besides this violent agonising pain; walking over rough ground seems to shake the whole nervous system, and riding and driving equally give pain. The first fifteen days and nights he had not one hour's sleep, though various anodynes were tried. Will some of my medical brethren kindly recommend something that may relieve, either through your valuable paper or by post to me.

Yours faithfully,

Bishop's Castle, Shropshire.
February 6th, 1875.

J. W. LANE, M.D.

COMMUNICATIONS, Enclosures, &c., have been received from—Dr. Thorowgood, London. Dr. Bayes, London. Dr. J. W. Lane, Bishop's Castle. Dr. Gongales de Velasco, Madrid. Mr. Kirks, Sheffield. MEETINGS OF THE LONDON SOCIETIES.

WEDNESDAY, Feb. 10th.—Royal College of Surgeons of England, 4 p.m. Prof. Erasmus Wilson, "On Dermatology."

HUNTERIAN SOCIETY.—7 p.m. General Meeting. 8 p.m. Annual Oration, by Dr. Gervis.

EPIDEMIOLOGICAL SOCIETY.—8 p.m. Dr. Squire: "Further Remarks on the Period of Infection in Epidemic Disease."

FRIDAY, Feb. 12.—Royal College of Surgeons of England.—4 p.m. Prof. Erasmus Wilson, "On Dermatology."

HUNTERIAN SOCIETY.—6 p.m. Annual Dinner at the Albion Hotel, Aldersgate Street.

CLINICAL SOCIETY OF LONDON.—8½ p.m. Dr. Vivian Poore will exhibit a Patient with Paralysis of Serratus Magnus. Dr. Southey will exhibit a Patient with Lepa Anæsthetica. Mr. Pugin Thornton: "Notes of a Case of exceeding Infrequency of the Pulse." Dr. T. T. Whigham: "Notes of a Case of Fatal Pleuro-pneumonia in an Opium-eater."

SATURDAY, Feb. 13th.—Royal College of Surgeons of England, 8 p.m. Hunterian Oration, by Mr. Frederick Le Gros Clark.

MONDAY, Feb. 15th.—Medical Society, 8 p.m. Ordinary.

TUESDAY, Feb. 16th.—Royal Institution, 8 p.m. Mr. E. Ray Lankester, "On the Pedigree of the Animal Kingdom."

PATHOLOGICAL SOCIETY.—8 p.m. Ordinary.

VACANCIES.

Royal Hospital for Diseases of the Chest, City Road. Physician. Honorary. Applications, with Testimonials, to be forwarded to the Secretary. (See Advt.)

North Wales Counties Lunatic Asylum. Assistant Medical Officer. Salary, £100, with board and furnished apartments. Testimonials to the Clerk to the Visitors, Denbigh.

Donegal District Lunatic Asylum. Consulting and Visiting Physician. Salary, £100 per annum. Applications, enclosing testimonials, to Dr. Merrick, at the Asylum. (See Advt.)

Seamen's Hospital, Greenwich. House Physician. Salary, £120, with furnished rooms, &c. Applications to the Secretary.

Bristol General Hospital. Physician Accoucheur. Honorary. Candidates should address the Chairman of Committee.

Lanely Union. Medical Officer for the Kidwelly District. Salary, £20, with fees extra. Application to the Clerk to the Guardians.

Alderbury Union, Salisbury. Medical Officer for the Workhouse and the District. Combined salary, £125, with extra fees. Address the Clerk to the Guardians.

St. George's Hospital, London. Lecturer on Comparative Anatomy. Candidates should apply to the Dean.

London Provident Surgical Appliance Society. Assistant Surgeon: Salary, £100 per annum. Attendance from 10 to 12 and 8 to 8 each day. Applications to the Secretary, 87 Gt. Ormond Street, Bloomsbury. (See Advt.)

Lewes Dispensary. Resident Medical Officer. Salary, £100 per annum. Applicants must address the Hon. Sec.

Haileham Union, Kent. Medical Officer for the Parish of Heathfield. Salary, £44, with fees extra. Applications to the Chairman of the Board of Guardians, Hellingly, Kent.

Canterbury Hospital. Assistant House Surgeon and Dispenser. Salary, £50, with board and lodging. Applications to the Secretary at the Hospital.

APPOINTMENTS.

BAIK, W. P., M.D. L.R.C.S. Ed., a Medical Officer for the South District of the Poplar Union.

BARTABLE, D. H., L.R.C.S.I., L.K.Q.C.P.I., a Medical Officer of South District of the Poplar Union.

CAREY, C., L.R.C.P. Ed., M.R.C.S. E., Medical Officer of Health for Bromgrove Country and Town Urban Sanitary Districts.

CHIBNE, J., M.D., an additional Examiner on Anatomy at the University of Edinburgh.

CLUGHORN, H., M.D., an additional Examiner on Botany at the University of Edinburgh.

CONNOLLY, P. R., L.K.Q.C.P.I., L.R.C.S.I., Resident Medical Superintendent to the Waterford District Lunatic Asylum.

COTTON, Mr. D. P., B.A., a House Surgeon to the Royal Maternity Hospital, Edinburgh.

DAVEY, C. J., M.R.C.S. E., Assistant to the Extra Physicians of the Royal Hospital for Sick Children, Edinburgh.

DAVIES, Mr. M. P., Public Analyst for Tenby.

DAVISON, T. V., M.B., Medical Officer to the Bridgenorth Infirmary.

DAVY, Mr. J., Assistant Resident Medical Officer to the Chorlton Union Workhouse.
 DEWAR, J., F.R.S.E., an additional Examiner on Chemistry at the University of Edinburgh.
 DUCKWORTH, DYCE, M.D., additional Examiner on the Practice of Physic at the University of Edinburgh.
 DUNMUR, J., M.D., additional Examiner on Surgery and Clinical Surgery at the University of Edinburgh.
 FERRIER, D., M.D., an additional Examiner on Medical Jurisprudence at the University of Edinburgh.
 FRASER, T. R., M.D., an additional Examiner on Materia Medica at the University of Edinburgh.
 GANGER, A., M.D., an additional Examiner on Institutes of Medicine at the University of Edinburgh.
 HALDANE, D. R., M.D., an additional Examiner on Clinical Medicine at the University of Edinburgh.
 LARGO, B. W., L.R.C.P.Ed., L.R.C.S.Ed., a House Surgeon to the Royal Maternity Hospital, Edinburgh.
 LLOYD, K. M., M.R.C.S.E., Surgeon to the Flintshire Dispensary.
 MACDONALD, A., M.D., an additional Examiner on Midwifery at the University of Edinburgh.
 M'INTOSH, W. C., M.D., an additional Examiner on Natural History at the University of Edinburgh.
 MAHOMED, F. H. A., M.R.C.P.L., M.R.C.S., Medical Tutor and Demonstrator of Pathology at the St. Mary's Hospital Medical School.
 PAYNE, J. F. M.B., an additional Examiner on Pathology at the University of Edinburgh.
 SINGLTON, F. E. C., L.R.C.P.Ed., L.R.C.S.Ed., Resident Medical Officer to the Royal Hospital for Sick Children, Edinburgh.
 SYMONS, G. S., M.R.C.S., Resident Medical Officer to the Chorlton Union Workhouse, Withington, Manchester.

Marriages.

JALLAND-MICKLEY.—On the 3rd inst., at St. Mary's Church, Aspeden, Wm. Hamerton Jalland, F.R.C.S., of York, to Ellen Maria, second daughter of Geo. Mickley, Esq., of Buntingford.
 MARTIN-JOHNSTON.—On the 27th ult., at Stephen's, Dublin, Brownlow Rudinge Martin, M.B., to Mary J., daughter of the late John Johnston, Esq.

Deaths.

CLARK.—On the 31st Jan., at Eliot Park, Blackheath, James Clark, M.D., aged 54.
 COOKE.—On the 22nd Jan., at Dawlish, A. L. T. Cooke, M.R.C.S.E., Surgeon-Major Madras Service, aged 54.
 JAMESON.—On the 1st Feb., Wm. Jameson, M.D., of Harcourt Street, Dublin, aged 72.
 LEAD.—On the 23rd Jan., at his residence, Woburn Lodge, Exmouth, W. H. Land, M.R.C.S.E., aged 75.
 MACLEOD.—On the 25th Jan., Wm. MacLeod, M.D., of Ben-Rhydding, Yorkshire.
 SMITH.—On the 26th Jan., Dr. Edward M. Smith, of Norwich, aged 51.

OLD COINS FOR SALE.—Gold, Silver, Copper, Saxon, English, Roman, Greek, &c. Lists free.—J. VERITY, Earlsheaton, Dewsbury.

FOR SALE.—The several Volumes hitherto published of the OLD and NEW SYDENHAM SOCIETY, together with the valuable plates issued up to this date. Also for SALE, a valuable Full Case of Surgical Instruments, by Weiss and Co., London, never used.—Apply at 28 Ely Place, Dublin.

PROVIDENT SURGICAL APPLIANCE SOCIETY,
 37 Great Ormond Street, Bloomsbury, W.C.—The office of ASSISTANT SURGEON to the above Institution is VACANT. Daily attendance from 10 to 12 a.m., and 6 to 8 p.m. Salary £100 per annum. Candidates (who must be registered practitioners) are required to send in their application, with testimonials, to the Secretary, on or before Thursday, the 11th February, and to attend at the Institution, on Friday, the 12th February, at 4 o'clock.
 J. P. CESAR, Secretary.

DONEGAL DISTRICT LUNATIC ASYLUM, LETTERKENNY.—The Governors of the above Asylum will, on WEDNESDAY, the 10th FEBRUARY, 1875, proceed to elect a gentleman duly qualified in Medicine and Surgery, to act as Consulting and Visiting Physician to the Institution, at a salary of one hundred pounds per annum.
 Applications, enclosing testimonials, &c., to be forwarded to Alex. Stewart Merrick, Esq., M.D., Resident Medical Superintendent.
 The personal attendance of candidates required on the day of election.
 (By order) HUGH STEVENSON, Clerk.
 Letterkenny, 27th January, 1875.

TO MEDICAL MEN AND CAPITALISTS.—HOTEL AND CONVALESCENT SANITARIUM.—The Proprietors of a furnished Hotel, in one of the most fashionable and frequented Marine Resorts, on which about £18,000 has been expended, possessing sanitary advantages not to be surpassed, and having a well-established first-class hotel business, with a view to its extension, are desirous to treat with one or more persons who can command £20,000.
 The special object proposed is to meet the particular requirements of the numerous Invalids and Convalescents who resort to the locality in a manner, to meet the cordial approval and patronage of the Medical Profession, for which there is every facility.
 Apply, in the first instance, by letter, to "MARINE," 41 Coney Street, York.

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

PATRON:—H.R.H. THE PRINCE OF WALES.
 This Institution was founded in 1839, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.
 To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.
 The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.
 Pupils are admitted free by election, or by payment of £25 per annum. A higher rate is payable for separate accommodation.
 Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.
 Each donation of Five Guineas gives the donor a life-vote.
 Annual Subscribers are entitled to one vote for each half guinea paid.
 An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.
 Full particulars as to the working of both Institutions, terms, &c. can be had at the office,
 40 MOLESWORTH STREET, DUBLIN,
 W. O'NEILL, Secretary.

DUBLIN INFIRMARY FOR DISEASES OF THE EYE and EAR, Ely Place.

Ophthalmic and Aural Surgeon:
 ARCHIBALD HAMILTON JACOB, M.D. Dub., F.R.C.S., Ex-Ophthalmic and Aural Surgeon to the City of Dublin Hospital.
 Consulting Physician:
 EVROY KENNEDY, M.D. (Hon. Cons.) T.C.D. and Edin., Fellow and Ex-President King and Queen's College of Physicians.
 Consulting Surgeon:
 GEORGE H. PORTER, F.R.C.S.I.; M.Ch. T.C.D. (Hon. Cons.), Surgeon in Ordinary to Her Majesty the Queen in Ireland; Fellow and Ex-President, R.C.S.I.; Senior Surgeon to the Meath Hospital.
 Obstetric Physician:
 JOHN CRONYN, M.D., F.R.C.S., Professor of Midwifery, Roy. Col. Surgeons; Ex-Assistant Physician Rotunda Hospital.

Work, Income, and Expenditure for Twelve Months

Annual number of Dispensary patients
Number of visits paid by such patients	5,547
Number of patients within the Infirmary	124
Number of operations performed	163
Total gross expenditure per bed per annum	£37 15 0
Average expenditure per intern patient	1 10 6

The Infirmary is wholly dependent on private benefactions, and is in debt to the Medical Officer. SUBSCRIPTIONS ARE EARNESTLY SOLICITED

BUTLER'S MEDICAL HALL, 53 & 54 LOWER SACKVILLE STREET, DUBLIN.

ESTABLISHED A.D. 1817,
 For Compounding Prescriptions and Supplying Genuine Medicines, is conducted, as formerly, under the careful superintendence of
 WILLIAM STARKEY, M.D.,
 Licentiate Apothecary

TASTELESS PILLS.—COX'S PATENT.

—Dated and Sealed, April 13, 1854.
 Surgeons and Chemists supplied with an excellent Aperient Pill (the formula for which will be forwarded), covered with a thin non-metallic film, rendering each pill perfectly tasteless, at its gross. Postage free. They present an elegant pearl-like appearance, and may be kept in the mouth several minutes without taste, yet readily dissolving, even in cold water, in an hour. Any formula dispensed and covered, and samples, with a list of pills, from 500 different forms which are kept in stock, will be forwarded free on application to
 ARTHUR H. COX and CO., Tasteless Pill Manufacturers, Brighton.

The Medical Press and Circular OFFERS UNUSUAL ADVANTAGES

FOR the insertion of announcements, from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c. it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.
 The scale of charges is as follows:—

Seven lines and under	£0 4 0
Per line afterwards	0 0 6
One quarter page	1 5 0
Half-page	3 10 0
One do.	5 0 0

 When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

The Medical Press & Circular.

ON NOXIOUS AND OFFENSIVE TRADES AND MANUFACTURES, WITH ESPECIAL REFERENCE TO THE BEST PRACTICABLE MEANS OF ABATING THE SEVERAL NUISANCES THEREFROM. (a)

By H. LETHEBY, M.B., M.A., &c.,

Professor of Chemistry in the College of the London Hospital; late Medical Officer of Health and Public Analyst for the City of London; and President of the Society of Medical Officers of Health.

PART II.

Size and Glue Making.—All sorts of gelatinous material, as fresh English fleshings (cuttings of hides) from tanneries, kip fleshings from abroad, calves' pates, and the cuttings of skins called "hide pieces," dried sinews, sloughs (bones inside horns), with other such offal and garbage, as well as fresh bones, are the raw materials from which size and glue are made. The fresh fleshings, as well as the clippings of others which contain fresh lime, are steeped for several hours in water acidulated with sulphuric acid. Old fleshings, in which the lime is killed by becoming carbonate, are merely washed with water; and these with the other glue-making materials are put into large open boilers, called "glue pans," with water, and are boiled for two or three hours by a naked fire, when glue is made, or by means of a steam coil, when size is the product, until they are dissolved. They are frequently stirred during this operation, in order that the fat may rise for collection. The liquid is then run off through a rough strainer into a tank, and allowed to settle for about half an hour, when it is either put into tubs and sent away as size, or it is allowed to set in wooden troughs, from which it is taken and cut up into blocks about a foot square, which are subsequently further divided by means of a wire into slabs, and dried.

(a) From a paper read before the Society of Medical Officers of Health, January 16, 1875.

The degree of concentration in making size is much less than that for glue, the point in the latter case being determined by the appearance of the cooked liquor upon a lump of alum. The residue in the glue pans is a mass of fibrous matter, called "skutch," which often contains enough fat to pay for another operation. The skutch is put into a boiler with enough sulphuric acid to dissolve the fibre (about 75 lbs. to a ton of skutch), and it is heated by high pressure steam blown into it. Under this treatment the fibre dissolves and so lets loose the fat, which rises to the surface. All these operations are offensive, and require to be managed with great care to prevent them from being a nuisance. The fleshings and other materials, for example, are frequently allowed to remain in heaps in hot weather until they putrefy, and the vapours from the glue pans and the skutch pans are exceedingly nauseous. It is proper, therefore, that the raw material should be used as quickly as possible, or be kept in covered tanks, and the vapours from the covered pans should be conveyed through condensers or coolers, and thence to the furnace fires.

Manure making.—Apart from the making of superphosphate of lime, which I shall describe directly, the manufacture of animal manure is generally a frightful annoyance, from the circumstance that it is generally in the hands of small capitalists, who have very little regard for the health or comfort of the community. The raw materials are of the most heterogeneous character, as fleshings, breakings, and other refuse from tanners, fellmongers, soap-makers, fat-melters, bone-boilers, glue-makers, &c., together with all sorts of waste from furriers, wool-spinners, hair-dressers, &c.; putrid fish, putrid flesh, and the offal of markets and slaughter-houses, all of which are indiscriminately used as the basis of animal manures; and these are treated in vats or boilers with sulphuric acid and steam—there being rarely much provision for the destruction or neutralization of the offensive vapours. Occasionally the operations are conducted in closed iron cylinders set vertically, so that the charge may be dropped into them at the top and let out at the bottom. When full they are made tight and submitted to the action of high pressure steam (from 30 to 50 lbs.),

which is blown into them for ten or twelve hours. In this manner the materials are perfectly disintegrated, and after standing for a few hours to cool, the liquid portion, consisting of water and fat, is first run out through a tap at the bottom, and then the solid parts are removed. Apparatus of this kind can be worked without annoyance to the neighbourhood, but if the manufacturer prefers to mix the materials in his own way, it should be done in a close chamber or cylinder with revolving arms, and with a contrivance for carrying the offensive gases to the furnace fire. Other operations, as *fish drying* and *smoking*, and the *preparation of albumen from blood and eggs*, also deserve notice as requiring attention and cleanliness to guard against nuisances.

Animal Charcoal Burning.—This until lately was a great annoyance to the inhabitants of the neighbourhood in which sugar bakers reside. Formerly the bones were burnt in iron retorts set in a furnace, without much precaution against the escape of the offensive empyreumatic vapours, and the red hot charcoal was cooled and quenched in iron boxes by means of water, whereby much sulphuretted hydrogen was evolved. The processes, however, at present in practice are planned with every consideration for the public comfort. The retorts are so constructed that the vapours from the ignited bones are carefully conducted to the furnace fire and are burnt; and the red hot bone block is received into specially designed coolers that do not permit of the access of atmospheric air, which would be destructive of the carbon of the bones. When the animal charcoal has become exhausted of its decolourising power, it is again burnt and revived in revolving retorts, or in well designed vertical cylinders, which do not permit of the escape of any offensive matter into the surrounding atmosphere, but discharge it into the furnace fire.

The roasting of coffee, chicory, and cocoa, if not properly managed, is offensive. The operation is performed in a revolving cylinder, a cage set over a coke or charcoal fire enclosed in a tight chamber, which is ventilated to the chimney shaft. In the case of coffee and cocoa the roasting operation is often performed in wire cylinders, whereas that of chicory, on account of the large quantity of powder produced, is always of sheet iron. The cylinders are about 4 feet long and 20 inches in diameter. They receive about a hundred-weight at a charge, and they are run into the roasting chamber upon a square axle, which supports them over the clear fire, about a foot above it. They are then set in gear, and turned by machinery at the rate of about fifty revolutions a minute. There are breaks in the interior of the cylinder to distribute the coffee or chicory during the roasting, so as to equalise the action. The operation lasts about thirty or thirty-five minutes for coffee or chicory, and half the time for cocoa; and the empyreumatic vapours go into the fire and up the chimney shaft. When the operation is finished, in the case of coffee and cocoa, the roasted berries are blown about by a blast of air, and this blows about a quantity of the outer covering of the coffee-berry (called *flights*), which are occasionally annoying to the neighbourhood. The loss of weight during these operations is from 14 to 16 per cent. for coffee, from 9 to 11 per cent. for cocoa, and about 25 per cent. for chicory. *Brown malt* and *roasted corn* are likewise roasted in much the same manner, and require that the empyreumatic vapours should be carried into the fire and be burnt.

There is another vegetable matter which in burning has lately caused offence to the neighbourhood in which the operations are conducted. This is the resinous matter obtained by the evaporation of the alkaline liquor obtained in the treatment of *Esparto grass and straw in paper-making*. The liquor is first evaporated in large close evaporating pans, which receive the full force of the fire above and below, and thus the vapours are carried forward into the chimney shaft. When the residuum is sufficiently consolidated, it is roasted in a furnace, for the purpose of burning off the organic matter and recovering the alkali. This operation has been forced upon the paper makers in

consequence of the difficulty of disposing of the spent liquors.

Within the last ten years a new branch of industry has sprung up in this country, on account of the permission to use sugar as well as malt in the production of beer. The sugar is called *saccharine* or *glucose*, or *grape sugar*, and it is generally made from the cheapest and most accessible kinds of starch. Rice starch is that which is commonly used in this country at the present time. The rice is crushed between rollers, and macerated in a vat with a little alkali for about twelve hours, during which time it is constantly stirred by revolving arms moved by machinery. In this manner the gluten of the rice is dissolved out of it, and the starch is set free. After standing quiet for about six hours the starch settles, and leaves a supernatant solution of gluten, which is generally thrown away. The starch is then transferred to another vat and treated with water acidulated with sulphuric acid. About 150 lbs. of acid (sp. gr. 1,850) and 1,500 gallons of water are sufficient for a ton of starch. The mixture is stirred like the last, and it emits a smell of rancid butter and grains (butyric and lactic acids). It is then run into a vertical cylinder, called a "digester," where it is submitted to the action of steam, at 20 lbs. pressure, blown into it for about half an hour. This converts the starch into glucose, and the solution is allowed to flow into a vat, where it is neutralised with powdered chalk, and kept stirred for about two hours, during which time the same offensive smell of butyric and lactic acids is evolved, and to a much greater extent. The clear liquor is next filtered through horsehair bags to separate sulphate of lime, and evaporated in vacuo to the consistence of a very thin syrup, which is filtered through animal charcoal in the usual way. It is then further evaporated in vacuo until it looks like honey. In this state it is poured into moulds and allowed to set. The yield of starch from the rice is as much as 80 per cent., and the yield of sugar is about 5 per cent. above the weight of the starch. The saccharine or grape sugar, when well made, contains from 80 to 82 per cent. of glucose, with only a trace of gum and mineral matter; and it is generally used by the brewer mixed with two parts or malt. The offensive effluvia from these operations are easily prevented by covering the vessels and ventilating them into the fire or chimney shaft.

Leaving these, which are the most important operations whereby sulphuretted hydrogen and organic vapours are evolved, I proceed to a class of manufactures which are nuisances by reason of the irritating acid vapours and gases which they produce; and these may be classified under different heads.

(To be continued.)

OSSIFICATION OF FŒTAL HEAD AND CONTRACTED PELVIS NECESSITATING CRANIOTOMY.

By WILLIAM DONOVAN, L.R.C.P., L.R.C.S.,
Fellow Obstet. Soc. Edin., &c., Medical Officer Carrigavarr
Dispensary, Cork Union.

VISITED Mrs. M., aged 40, on the 24th of January last, at about 1 o'clock, p.m., who had been in labour for about fourteen hours. On making an examination, I found the head presenting at brian of pelvis, and everything apparently right. Seeing no necessity for interference, I left, desiring the midwife to send for me if required. I was called again at 11 o'clock p.m., and on examination found the head in the same position as it was on my former visit. These facts led me to make inquiry as to her former labours, when the following facts relative to the woman's history were elicited: Mrs. M. had been naturally delivered of seven healthy children, all of whom survived. In her eighth confinement she had to be delivered by instruments at the expense of the child's

life. In her ninth labour she was delivered by craniotomy, under chloroform, by two medical officers of Cork City Dispensary, now four years ago. With these facts before me, and with no professional assistance within some eight or nine miles, and symptoms of exhaustion becoming apparent in the patient, I proceeded at once to apply the long forceps, which I succeeded in doing after some trouble. On making traction in the usual way I was enabled to bring the head into the cavity of the pelvis, where it became so impacted that all my efforts, aided by strong labour pains, were unable to move it further. The forceps appearing to have no compressing power on the head, and the woman becoming more exhausted, I removed the forceps and examined the head carefully, when I became aware of two circumstances—first, that the pelvic cavity was abnormally contracted, and secondly, that the cranial bones of the fœtus were fully ossified, the sutures and fontanelles being scarcely definable. Having now spent some six or seven hours in a miserable cabin, and beginning to feel rather done up from heat, bad air, and long-continued exertion, and feeling confident that labour could not be completed except by craniotomy, the woman herself and her husband consenting, I proceeded to perform the operation, and completed delivery with the blunt hook or crochet at 6 o'clock a.m. Hæmorrhage having set in after the removal of the placenta, and the patient showing a tendency to syncope, I administered twenty drops of tincture of Indian hemp and some spirits and water. Urgent symptoms being relieved, I left the house at 7 o'clock. The woman made a rapid recovery, the only unpleasant symptom arising being retention of urine, which being relieved, no further attendance became necessary, the woman being now quite recovered.

CASE OF CRANIAL INJURY. (a)

By E. H. BENNETT, M.D.,

Professor of Surgery in the University of Dublin.

THE individual whose calvaria Dr. Bennett showed the Society was about 19 years of age. It appeared that he was engaged during last summer in carting rubbish from a building which was undergoing repairs. While thus employed a scaffold-pole fell and struck him on the side of the head. By the force of the blow his head came in contact with a heap of bricks, so that, so far as the history of the blow went, he was struck on both sides of the head, and in the absence of any definite wound, they were doubtful as to which was the most serious injury. The man was stunned by the blow, but recovered himself in a few moments, and almost as quickly as he fell, and his fellow-workmen assisted him to rise; he recovered consciousness. He was given a glass of whisky, which he vomited. This occurred between half-past 11 and 12 o'clock in the day. After the accident he went to Townsend Street, about a quarter of a mile distant, to the stable; he brought the horse in, unharnessed him, and put him into his stall. No one would appear to have come in contact with the injured man for about two hours. At 2 o'clock his fellow-workmen found him lying in the stall, and they, assuming he was drunk, left him there; so he remained until about 5 o'clock in the evening, and then he was brought to Sir Patrick Dun's Hospital. When he (Dr. Bennett) saw him, about 6 o'clock, his breathing was stertorous, and he was paralysed on the left side. His pulse was slow and feeble, and his respiration was so slow that every now and then it seemed as if his last breath had been drawn. On examining the cranium he failed to determine anything that would account for the symptoms. Taking into account the history of the suddenness of his recovery, and the fact that the vomiting was followed by an hour, at all events, and perhaps more, of sensibility, and then the second relapse into unconsciousness, he thought these circumstances pointed to the conclusion that his condition at the time of admission was due to inter-cranial hæmorrhage, and that in all probability an important one of the meningeal vessels was lacerated; but to

determine the side was impossible, considering the diffused nature of the wound. He died in about an hour after Dr. Bennett saw him. The autopsy was made on the following morning; and they found, on raising the scalp, that blood effusion was present in the whole of the vertex and in either temple. They also detected a fissure passing along the coronal suture right down to the temple. On sawing the skull across they found a blood-clot, one of the largest he had ever seen. It lay directly over the track of the meningeal vessels, and of course compressed the surface of the brain so as to form a deep hole or *fossa* in it. There was also a small fissure in the periosteal layer of the dura mater. The case was of interest owing to the intervals of sensibility after the injury was sustained and the other details which were so well-marked.

CASE OF ELEPHANTIASIS ARABUM. (a)

Under the care of W. J. WHEELER, F.R.C.S.,

Surgeon to the City of Dublin Hospital.

THE subject of this case was a woman, 30 years of age, who was admitted into the City of Dublin Hospital under his care on Oct. 16th, 1874. She had suffered from the disease for eighteen years. The disease began by a pain in the foot. When the patient was 10 or 11 years of age the ankle then swelled, again subsided, and again enlarged. She suffered during this period from a fever known as elephantoid fever. The crevice, as it was called by Virchow, formed at the inner malleolus and the folds of skin lying on one another caused ulceration. Amputation was performed on Nov. 7th. The size of the sound limb as compared with the diseased was as follows: Sound—round ankle, 8½ inches; round calf, 13 inches; round dorsum of foot, 9½ inches. Diseased—round ankle, 20 inches; round calf, 26½ inches; round dorsum of foot, 18½ inches. In this case the limb was immensely developed, the fascia over the gastrocnemius muscle was much thickened, its elements more lax than normal. The tunica adventitia of the blood-vessels was thickened; the other coats were healthy.

CASE OF RUPTURE OF THE LIVER. (a)

Under the care of JOHN HAMILTON, F.R.C.S.,

Surgeon to the Richmond Hospital.

THE patient was a child, admitted into the Richmond Hospital on the 16th of the month. Ten minutes before admission a wall had fallen on the child and crushed it, and on reaching the hospital the child was in a moribund state; its face was deadly pale, the extremities cold, and the action of the heart feeble. He died fifteen minutes after admission, and twenty-five minutes after the accident. On the chin there was a deep cut, and there were severe scratches about the legs, but there was no abrasion or bruise, or, in fact, any sign of injury to the trunk, chest, or abdomen. The latter was a point in the case which should be borne in mind. Forty-eight hours elapsed before the body was examined, and when the abdomen was opened and the viscera inspected no lesion was discovered in any except the liver, and the lesions there were of a very extensive nature. On the posterior surface it would be seen that the right lobe was nearly entirely torn away from the body of the organ. The most important of the lesions was a great rent which went obliquely to the right lobe and nearly separated the liver into two parts. The injuries were all on the posterior surface of the liver. Mr. Stack observed that these extensive lesions and bruises were exactly opposite to the prominent part of the spine, and he therefore came to the conclusion that the soft walls of the belly had yielded before the weight and force of the falling wall; and that the resistance of the spine on the one side and the weight on the other had torn the liver between them. He (Mr. Hamilton) had no doubt this was the case. Some years ago he exhibited to the Society the liver of a sweep who had fallen down a chimney and whose right side as he fell came in contact with a projecting part of the wall of the chimney. He was admitted suffering from intense pain in

(a) Abstract of a communication to Dublin Pathological Society, reported for the MEDICAL PRESS AND CIRCULAR.

(a) Abstract of a communication to Dublin Pathological Society, reported for the MEDICAL PRESS AND CIRCULAR.

the belly, and lingered two days and a half, when he died. He had suppression of urine. It was hard before death to make out what was the nature of the injury, but it was supposed that the kidney was injured. When the abdomen was opened, however, in that case, the injury was found to be in the liver, which was torn extensively, just as in the case now before the Society. As in the present instance, there was no sign of bruise or abrasion on the abdominal walls. In the case now before them the hæmorrhage amounted to twenty-six ounces of blood, found in the cavity of the belly. The hæmorrhage was also very extensive in the sweep's case. Owing to his stronger constitution, he survived the length of time already mentioned, his death being caused by the excessive shock and the great injury which this important organ received.

CASE OF EXCISION OF THE KNEE. (a)

Under the care of Dr. HAYES,
Surgeon to the Mater Misericordiæ Hospital, Dublin.

THE patient was an inmate of the Mater Misericordiæ Hospital, a girl, 18 years of age. About eight years ago she was thrown from a car on to the road, falling on her left knee, and being thereby rendered insensible. The patient stated that her head did not come in contact with the ground, but that it was owing to the excessive pain in her knee that she was rendered insensible. She was carried home, and when she recovered consciousness sickness of stomach occurred. She was able to move about some days afterwards, but the knee became swelled and painful. This continued for a month, when the pain became much aggravated, and prevented her walking. She now consulted a doctor, who said that the knee had been dislocated, and the patient stated that the doctor reduced the dislocation, but told her not to walk on the leg. A few days afterwards, however, she gave the knee a jerk, but took no notice of it until, at the end of six weeks, she found it necessary to consult the same doctor, who told her that dislocation had again occurred, but on this occasion he failed to reduce it. At this time she was not able to walk, and the pain continued. Three years ago she got startings in the knee at night, chiefly in the early part of the night. In July, 1874, she came to Dublin, and consulted his colleague, Dr. Cruise, being admitted into the hospital under his care. He (Dr. Cruise) did everything possible to relieve the pain and bring the limb into a proper position, the knee being now flexed, and keep the joint at rest. There was no history of a strumous family. She left hospital in July, having had an attack of erysipelas while there. She was readmitted in September last, under his (Dr. Hayes') care, when the following was her condition: The joint was somewhat globular in shape, felt soft and pulpy, the patella being movable. He (Dr. Hayes) excised the joint. At the first glance it seemed to present the appearance of very little disease. In the outer condyle of the femur they had the chief point of ulceration and erosion of the cartilage, and there was evidently a stratum of enlarged vessels filling a considerable portion of the cartilage. The surface of the patella was also in an abnormal condition. The inner facet was covered with fibrous tissue crossing the surface, and there was also a small ossified mass of bone. The condition of the synovial membrane was morbid and pulpy, and the degeneration of Sir Benjamin Brodie was well marked. The patient suffered intense pain, and could hardly bear the slightest examination of the bone.

CASE OF PLEURITIS (a)

Under the care of Dr. NIXON,
Surgeon to the Mater Misericordiæ Hospital, Dublin.

Dr. NIXON showed specimens taken from the body of a patient who had died in the Mater Misericordiæ Hospital of pleurisy. With the usual treatment the man seemed to get on very well, but bronchitis set in, and he suffered from sleepless nights. One night especially it was thought he was dying, as he sat up in the bed, gasped for breath, and became livid in the face. On the following morning 4½ ozs. of clear

serous fluid was drawn off from the right side of his chest. The patient coughed a good deal. Shortly afterwards severe vomiting set in and continued for three hours, after which he seemed to slightly improve. On the same night, however, the pulse became very quick, and the respiration increased in rapidity. When examined at 12 o'clock that night the respirations were 70, and the pulse 150. The man gasped for breath, and this continued until the following morning, when the patient, who was sitting up in bed with a livid face and with greatly obstructed breathing, died. The post-mortem examination showed that the parietal portion of the pleura was greatly thickened, and a layer of lymph covered part of the visceral portion. The right side of the pleura contained three or four quarts of serous fluid. The heart was found intimately attached to the chest-wall corresponding to the left nipple. Prior to the operation of tapping some doubt existed as to whether or not there was fluid in the pericardium. The heart was intimately attached to the parietal portion of the pericardium, and in the situation of the attachment from 18 to 20 ozs. of bloody serum were found. The right lung was intensely injected with blood, perfectly airless, and sank rapidly in water.

Transactions of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JANUARY 25TH, 1875.

C. J. B. WILLIAMS, M.D., F.R.S., President, in the Chair.

ON THE TEMPERATURE OF PHTHISIS PULMONALIS AND ON THE VARIOUS CONDITIONS INFLUENCING IT.

By C. THEODORE WILLIAMS, M.A., M.D., F.R.C.P.

THE author, after briefly reviewing the labours of Jochmann, Lebert, Küchenmeister, Ringer, Wilson Fox, and others on the thermometry of phthisis, proceeded to demonstrate the reasons why hitherto no definite laws governing the rises and falls of the temperature in the disease had been discovered; the main point being the comparatively few observations taken *per diem*, and the acute and exceptional character of the cases under observation. A clinical and pathological account was then given of one hundred and four consumptive patients, inmates of the Brompton Hospital, and, therefore, subjected to the same equable atmospheric and hygienic conditions, in all of whom the temperature was taken at least five times, and in many of them seven, ten, and twelve times daily, for periods varying from seven to thirty days. The patients were sixty-three males and forty-one females, embracing all acute and chronic forms of the disease except acute tuberculosis. The temperatures were taken for the most part in the axilla, and in some instances, for comparison, in the mouth, by the clinical assistants and by Dr. Williams himself, with thermometers manufactured by the best makers. These observations amounted in number to between four thousand and five thousand. To ascertain more fully the exact thermometrical phenomena of the disease, and especially the night changes, in twelve cases an hourly record was carried out for twenty-four consecutive hours, and in some instances it was repeated for a second similar period. The state of the pulse, respiration, skin, bowels, and urine was likewise noted; as also the time of meals and the amount of food taken. The cases are classified in the following manner, according to stages: 1. First stage, active (where formation of tubercle was taking place); 2. First stage, quiescent; 3. Second stage, that of softening; 4. Third stage, active (with increasing excavation and tuberculisation); 5. Third stage, quiescent (or chronic cavity). The results of the analyses under these headings were then given, and the temperature at each of the hours of observation, viz., 8, 10, and 11 a.m., 2, 5, 8, 10, 11, and 12 p.m., as also the intermediate day temperatures occasionally taken and the night observations. The media, maxima, and minima of each stage were stated, and tables and charts were exhibited to explain more fully the method of calculation and the results arrived at. The influence of the states of

(a) Abstract of a communication to Dublin Pathological Society, reported for the *MEDICAL PRESS AND CIRCULAR*.

consolidation and of tubercle formation, of softening and of excavation, as well as extension of disease, on the temperature, were dwelt upon, and illustrative instances of each given; the pathological state being proved in many cases by post-mortem examinations. The chief conclusions as to the diurnal temperature of the disease were as follows. In a large number of chronic phthisis cases, the temperature is normal or subnormal, sometimes falling to between 93 deg. and 94 deg. Fahr., a continuity of low temperatures being most marked in the first and third quiescent classes. In pyrexial cases, the temperature is seldom very high, 104.6 deg. Fahr. being the highest recorded. In the majority, a marked rise takes place after 2 p.m., and a rapid fall occurs after 10 p.m., which continues throughout the night, until its minimum, sometimes as low as 94 deg. is reached before 7 a.m.; a slight recovery is then perceptible, the normal being seldom, however, attained before 9 or 10 o'clock. This temperature wave may be shifted a few hours, the rise taking place later in the afternoon, the high temperature being maintained farther on into the night, and the lowering consequently delayed by some hours. Any continuous rise of temperature is followed by a certain amount of collapse, thought not always to a corresponding degree. The disease in all its stages shows the post meridian rise and the nocturnal fall, with the early morning collapse temperatures; and that the latter is a characteristic of phthisis is proved by Dr. Williams' observations on a healthy man (placed under similar conditions to the consumptive patients), in whom the night temperatures did not fall materially below the day ones. The first stage exhibits a more gradual rise and fewer extremes of temperature than the third. In the third stage the temperatures are the highest and the lowest, both afternoon pyrexia and nocturnal collapse being most strongly marked, the one having been known to rise to 104 deg. Fahr., the other to sink to 93 deg. Fahr., thus exhibiting a range of 11 degrees. The second stage shows intermediate thermal features between the first and third stages, active. Tubercle may form, and the various processes of lung-disorganisation may proceed uninterruptedly without apparently causing any considerable rise of temperature, and may even be accompanied by a subnormal temperature, this being probably due to the collapse influence on the constitution. Many of the variations in the phenomena are to be explained by the formation of pus, the liquefaction of adjoining tissues, the imprisonment of the purulent and caseous compounds, and their subsequent evacuation by expectoration. Phthisis has a distinct temperature course, marked, on account of these changes, by great intermissions; but the idea that in each case it depends on individual idiosyncrasy is founded on imperfect observation. In all cases, two principal agencies appear to determine the temperature course: first, an excessive action of the natural processes by which the body heat is maintained; secondly, the influence of collapse, proceeding from the well marked weakening of the constitutional powers in phthisis. These two agencies are continually struggling for the mastery, and the result of this conflict is the temperature course of the disease. The influence of the first is seen in the rise in the afternoon and evening well marked in the active forms of all three stages, and regularly recurring day after day for long periods; the influence of the second was shown in the rapid nocturnal fall and low temperatures of early morning; the collapse influence was also seen in the subnormal day temperatures, occasionally occurring in all stages of the disease, and even where the active processes of lung tuberculation, of softening, and of excavation may be taking place. It is, however, chiefly noted in the quiescent forms of the first and third stages. When low temperatures accompany active forms of the disease, it is probable that the collapse influence is stronger than the pyrexial, and, therefore, masks it. When the chart shows occasional fitful variations, these agencies are, perhaps, evenly balanced, and may alternately prevail, as is witnessed in the end temperatures of consumption; and to these derivations, noticed in advanced cases, may be ascribed the prevailing, but erroneous opinion of phthisis having no definite temperature courses. The author concluded with a careful comparison of weights of the above patients, with their temperatures, and made some deductions therefrom.

Dr. WILSON FOX for some years had attempted such records, but had not made an analysis of the results. It appeared that the highest evening temperature was at 5 p.m.; but there seemed to be this difficulty, that on no two days at the same hour was the temperature alike. For instance, the temperature at 8 a.m.—the lowest—might be

in successive days 97 deg., 98 deg., 99 deg., and 100 deg.; and, at 2 or 3 p.m., it might be 101 deg., 102 deg., or 103 deg. These facts must influence our ideas as to treatment; they must show that the use of therapeutic agents (excepting the cold bath) must be guided by the vitality of the patient rather than by the thermometer. Phthisis was one of the exhausting diseases; chronic suppuration was another. In a case of chronic suppuration following delivery, the extreme variation of temperature was 10 deg. He believed that Dr. Burdon Sanderson regarded great variations in temperature as indicative of suppurative fever. He thought that it was not the existence of pus, but the process of its formation, that led to pyrexia. The more inflammatory processes tending to destruction took place, the more frequent were the variations of temperature. There was, however, an exception to this in pneumonia. It was not yet possible to give the reasons for the variations in individual cases; but Dr. Fox believed that at some future day this would become possible.

Dr. DOUGLAS POWELL objected to Dr. Williams' view of the unity of phthisis in all its forms. When cases of all kinds were mixed, the mean results obtained were less valuable than they would be if a classification were made. The great fact which had come out was the great fall of temperature in the early morning hours; and this would probably be of much importance in treatment. This fall must be due, he thought, to exhaustion; it might, perhaps, be avoided by feeding the patient at night. He asked whether Dr. Williams had made any observations as to the effect of food in modifying the fall of temperature. It had been suggested that the best plan of preventing night-sweats was to feed the patients.

Dr. DRYSDALE had observed, in the North London Hospital for Consumption at Hampstead, that, for a month or two at a time, almost every patient increased in weight, no matter what their temperature might be. He agreed very much with Dr. Williams in his objections to Niemeyer's doctrine of the varieties of phthisis. The only variety that he sometimes met with was one which he attributed to syphilis. He thought that, in miliary tuberculosis, the temperature would be high in proportion to the number of tubercles.

Dr. T. H. GREEN did not think the pyrexia in the third stage was due to disintegration and softening, but to the presence of the first stage of the disease in some other part of the lung. He asked whether the thermometer would indicate the occurrence of an infective process in phthisis.

Mr. HERBERT PAGE said that the curves of temperature in the first stage of phthisis resembled what was seen in surgical cases, where the occurrence of suppuration was marked by similar variations.

Dr. LEARED asked whether the observations on temperature would assist in the diagnosis of the stages of phthisis.

Dr. SYMES THOMPSON said it had been stated that phthisical patients presented idiosyncrasies which rendered thermometric observations futile as regarded treatment. He thought that it had been proved that quinine was a powerful agent in keeping down a high elevation of temperature; but how far real good was done by preventing a rise of temperature was another question.

Dr. CURNOW had taken the temperatures of several of Dr. Thompson's patients in the Brompton Hospital by day and by night. There was great difficulty in finding the averages, although the temperatures touched at certain parts of the day. In some cases complicated with diabetes there was no rise of temperature. As to the influence of the formation of pus, similar fluctuations of temperature were observed in cases of softening of the brain after embolism. The same was the case in separation of fibrin in the blood, leading to metastatic abscesses.

Dr. THEODORE WILLIAMS, in reply, stated that, though it was true that it had been known that morning temperatures were lower than evening in consumption, the exact temperature course, with its variations, was now depicted for the first time, with its remarkable afternoon rise, and still more striking nocturnal fall. As to irregularity of temperatures taken at the same hour, this was not more the case in phthisis than in health, where the observations varied considerably; but variations of this kind in phthisis were sometimes to be explained by a shifting of the whole temperature course by an hour or so. He was strongly of opinion that the chart of the third stage (active class) was typical of suppuration; and various speakers had strengthened this

conclusion by adducing evidence from other suppurative diseases, medical and surgical. The low temperature of the early morning was due to exhaustion, and might possibly be avoided by feeding the patient through the night; but his observations on this point were not yet complete. Whether the local infective process in the lung from a caseous centre could be detected by temperature, he could not tell; but, in several instances where general infection of the system had taken place, it had been characterised by a chart resembling that of pyæmia. He was aware of his classification being rather too simple; but, the results of investigations on this point having been confirmatory of the unity of phthisis, he preferred a few distinct classes, with well marked features, to a number of small divisions hardly to be distinguished from each other. The thermometer might sometimes detect the formation of tubercle before physical signs did; but, on the other hand, tubercle might form without any rise or fall of temperature. The best hours for clinical records in phthisis were: for the low temperatures, from 3 to 6 a.m.; for the high, from 5 to 8 p.m.

ARMY MEDICAL REPORTS.

III.

THERE is an Appendix to the Blue-Book, entitled the "Army Medical Report," which contains several interesting essays by Drs. Parkes, Fleming, Warden, Monro, Alcock, Don, Tullock, O'Leary, Slaughter, and Longhurst.

The first essay is a report on hygiene for the year 1873, from the skilful pen of Professor Parkes, of Netley. In this report we find it noticed that Mr. Wanklyn, in his account of the analysis of milk, recommends determining the solids by taking out 5 c.c. and evaporating in a small flat platinum dish in a water bath; in three hours the milk is dry, and with a good balance the error falls only in the second place of decimals. After the residue is obtained the fat may be dissolved with ether, but as 5 c.c. gives a small quantity, Mr. Wanklyn prefers taking 10 c.c. of milk, evaporating nearly, but not quite to dryness, and stirring (which is not necessary in the former case) and then dissolving in ether, not less than 50 c.c. (and generally more) of which is necessary. By putting an inverted small glass funnel over the milk and ether, in the platinum dish, a sort of flask is formed, which facilitates the extraction of the fat. After pouring off the ether and its evaporation, by means of a water-bath, nearly to dryness,

the dish is heated to 212° (in a hot-air chamber, or by vapour) to drive off a trace of water and alcohol, and is then ready for weighing.

By this process the solids are divided into two parts—fat, and solids not fat. He assumes that 100 c.c. of milk contain 9·65 grammes of solids not fat (casein, lactine, and ash), and he takes this as a rigid standard of normal milk, which, if departed from, indicates adulteration.

In order to determine how much real milk a sample of milk contains, he divides the "solids not fat" by ·0965. To determine the amount of fat removed by skimming, he recommends us to divide the percentage of "solids not fat" by the percentage of fat. The rule given that the added water may be estimated by considering 9·3 per cent. as the proportion of "solids not fat," Dr. Wanklyn asserts that in ten analyses made by himself of pure milk, the lowest amount of total solids was 11·8, and the highest 14·07. It is clear that when cows, as they occasionally do, yield milk containing as much as 16 per cent., a good deal of water might be added and no adulteration detected.

Dr. Parkes is of opinion that the standard of 9·3 "solids not fat" would break down in a court of law, and he thinks it better to assume the possible minimum amount of total solids to be equal to 10 or even 11 grammes per 100 c.c. of milk. No analysis of undoubted cow's milk he is acquainted with ever detected a less amount of solids than 10 grammes, and 11 is extremely rare. So that we should, he urges, be absolutely safe in calculating the addition of water from the standard of 10 grammes in 100 c.c., viz., that every deficiency of a gramme below 10 grammes per 100 c.c. implied the addition of 10 per cent. of water, and that conclusion could be stood by. It could also be explained to the magistrate that, as a rule, the solids in milk are rather 12 than 10 per cent.

Mr. Wanklyn discourages the plan of taking the specific gravity of the milk, and, no doubt, when it can be done, the determination of the solids by weighing them is the best. But when the specific gravity is taken with due regard to temperature and amount of cream, it gives most useful information, and is a great control over the tradesman. If a specific gravity of 1028, at a temperature of 60°, and cream to the amount of 8-100 be ensured, no great amount of water has been added. Mr. Wanklyn without promising complete accuracy, finds that 0·2 gramme of fat equal one gramme of cream; and he finds the amount of water in cream to vary from 50 to 72 per cent., and of fat from 19 to 44 per cent. The casein, sugar, and ash in cream vary from 5·63 to 14·77 per cent. As cream thus varies in composition, he is not clear as to the value of the creamometer. He proposes to determine the casein in milk by means of the "albuminoid ammonia test," acting on 5 c.c. of milk in 100 c.c. of water, and proceeding as in water analysis; every part of casein gives ·065 parts of ammonia; 100 c.c. of milk give ·26 grammes of albuminoid ammonia. He estimates the ash at between ·7 and ·8 grammes in 100 c.c. of milk.

In the *Indian Medical Gazette*, July 1, 1873, Dr. Macnamara has carefully analysed milk in Calcutta. He determines the total solids by exposing 5 grammes to the temperature of 212° for three hours, and then finds the ash. He gets the sugar by taking 2 c.c. of the milk: 3 or 4 drops of acetic acid and 40 c.c. of spirits of wine. The flask is then corked, shaken, and left to stand 24 hours,

when it is filtered, and the residue over the filter washed with 60 c.c. of a mixture of equal parts of water and spirits of wine. The fluid is then evaporated to a syrupy consistence and taken up by 100 c.c. of distilled water, and the amount of sugar is determined by Fehling's test. Dr. Macnamara finds that in Bengali cow's milk there were 15.22 per cent. of solids, 5.5 of casein, 4.98 of fat, 3.98 of sugar, .76 of ash, and 84.78 of water; whereas the milk bought in the bazaar contained only 4.88 per cent. of solids.

Dr. Willard, of the Cornell University, U.S., describes in detail the liability of milk to a peculiarly bad behaviour, refusing to be controll'd in spite of all our care and caution, with respect to cleanliness, &c., a point which, in the manufacture of condensed milk, has especially to be attended to, as the success of the condensing factory depends entirely upon the milk being fine flavoured and clean and healthy, free from droppings of the stable, &c. He alludes to the investigations of Haller and Pasteur on the change in milk wrought by living organisms, as from cesspools, decomposing and putrid animal matters.

Mr. Tester, of Oneida, says that the milk from cows which have breathed foul emanations is not fit for making cheese.

Professor Law, of Cornell University, one day remarked during the hot weather, a peculiar ropy appearance in the cream which had risen on the milk. He examined it under the microscope, and found it filled with living organisms of a character quite foreign to good milk. On looking through the pastures he found that the cows, from lack of clean running waters, were compelled to drink from a stagnant pool. He found the same organisms in the water as he had detected in the cream, and also in the blood of the animals. The temperature of the cows was found to be above the normal.

Dr. Parkes with justice observes: "The facts above stated are of importance far beyond the effect on the manufacture of milk. They show the influence of water swarming with organisms in a much clearer way than can be obtained in towns in men. From drinking the water of these stagnant pools the cows were made feverish, and delivered milk containing the same organisms as the water, and as when a drop of this stagnant water was put into good milk the organisms developed in infinite numbers in a short time, it can hardly be doubted that they did not merely pass in a living state through the bodies of the cows, but must have grown there, and thus caused the feverishness. We have, in fact, an instance of these small organisms giving rise to fever and passing off with a secretion. It seems to me a pathological fact of moment, and we may be sure that the same thing will occur in other animals."

THE SYSTEM OF DISTRIBUTION OF THE DUBLIN HOSPITAL SUNDAY FUND.

THE friends of the Dublin Hospital Sunday Fund were called together last week by advertisement "to consider the rules to be adopted for the management of the Fund for the year 1875." We will therefore take occasion to direct public attention to the distribution of the 1874 Fund, which we submit was entirely partial and inequitable and which we should have hoped to see completely changed before the '75 Fund is dealt with.

Our readers will recollect that the Distribution Committee were instructed by the Council—

(1) To allocate the money at their disposal to each co-operating hospital in the proportion—*firstly*, of the amount of private subscriptions received by the institution; *secondly*, of the work done by it during the previous year.

(2) To give credit as "work done" only for intern patients, extern midwifery cases, and extern accidents.

The Distribution Committee carried out these instructions to the letter, and, we think, even exceeded the intentions of Council in restricting the benefits of the charity to what we may call "subscription" hospitals and to intern work. They at once divided two-thirds of the entire fund in proportion to the private subscriptions of each hospital, allocating most money to those which enjoyed most private support; and cutting off with a pittance those which from circumstances of locality, or for other reasons, received little voluntary help. Having thus disposed of the major part of the fund, they divided the remaining third according to the work done, but in doing so, excluded almost altogether from consideration the relief afforded to the outside poor, giving credit for 1,000 accidents, or 500 midwifery cases, as equivalent only to the maintenance of one single bed. We submit for the judgment of our readers whether this allocation of the fund was not absurd and inequitable. Why should "subscription" hospitals be thus placed at so great an advantage to those which effect, perhaps, more valuable medical relief amongst the sick poor? And why should the surgical care and expenditure upon a poor man, whose circumstances may not permit of his going into hospital, or on a poor woman who is confined in her own room, be assessed as of no value at all? The hospital which has the largest private subscription list will probably be found in a fashionable and opulent locality, where there are few of the destitute sick. The hospital which provides for the wants of the inhabitants of the city slums will probably receive very little voluntary support, and yet on the principle which was adopted, the latter institution—with heavier demands on it and less resources—is cut off with a shilling, whilst the wealthy and well-supported hospital receives the lion's share.

The Hospital Fund Council have, we think, made a serious mistake in depreciating the value of extern relief to the extent that they have. Is the daily attendance and medicine which is afforded to the father of a family who is not so ill as to be entirely incapacitated from work, and who *must* make an effort to remain at his business, or else see his family starve, of no value as a work of charity? Is it not a form of medical relief just as necessary and as praiseworthy as the nurturing of chronic colds or rheumatic joints in the wards of an hospital? We regard it as far more useful and important, and therefore submit that it is a monstrous injustice to refuse any credit at all for the majority of such cases, and to estimate 1000 such accidents, or 500 extern midwifery cases as equivalent to one bed maintained in the house.

Our principal object in calling attention to the subject is, however, to protest against a system of distribution which takes little or no cognisance whether an hospital is administered with careful economy or with gross extravagance, which, in [other words, takes no care that the

Hospital Fund shall go to the sick poor rather than to unnecessary salaried officials. We maintain that the first duty of the Council is to see that the money shall produce the maximum amount of relief to the destitute sick themselves, and that the least proportion of it shall be applied to objects which afford them little or no benefit; when we tell our readers that in some of the hospitals which received a considerable share in the fund more than three-fourths of the money goes in establishment expenses (the gain from which is hypothetical), while in other institutions which afford relief just as good in quality, and just as abundant in quantity, the "establishment," including nursing, absorbs less than one-third.

If our readers will refer to the Report presented to Parliament by the Dublin Hospital Board, which appears in the "Irish Medical Directory" for this year, they will find it stated that one of the hospitals which received a grant from the Fund expended more than £1,200 upon officials, &c., who were employed to disburse the munificent sum of £379 for the sick poor. Another institution appropriated more than £3,000 to an establishment of functionaries charged with the disbursement of £1,300 for the maintenance and medical treatment of the patients.

Thus it appears that of every £1 which the Dublin Hospital Council handed over to these institutions 15s. 6d. went in one case, and 14s. in the other to purposes not directly (with the exception of nursing) of any value to the patient. In these hospitals the sick patient costs respectively £75 and £67 a year, a sum for which he or she might be liberally boarded out in any genteel lodging-house. That such extravagance as this is entirely unnecessary is proved by the fact that other hospitals—equally efficient in all respects—pay only about 7s. in the £ for establishment charges, and though the cost of maintaining a bed in them is less than half that which its support costs in the more expensive institution, yet these more economical hospitals disburse upon the patient himself a much larger sum than is afforded by the more expensive institution.

We hold that this should be the most important consideration in awarding a grant, and it seems to have been wholly forgotten. The public, from whose pockets the charity comes, care nothing about the source from which the income of an hospital is derived. They are anxious only that what they give shall bring the greatest benefit to the sick poor, and that the least proportion of it shall go in other expenses. We think that the system adopted for the last distribution affords no such guarantee, and we therefore deeply regret to observe that it has been re-enacted. We shall return to this subject next week.

Notes on Current Topics.

Temperature in Phthisis.

At the meeting of the Royal Medical and Chirurgical Society of London, on the 26th January, a long paper was read by Dr. Theodore Williams on "Temperature in Phthisis." The results of a numerous set of observations made by the author, at the Brompton Consumption Hospital, were that there was a period of low temperature

observable, usually early in the morning, in cases of chronic phthisis, and a period of highest temperature between 2 and 10 p.m. In the majority of cases at all stages a marked rise takes place after 2 p.m., and a rapid fall after 10 p.m., which continues throughout the night, and reaches the minimum, which may be as low as 94 before 7 a.m.

Dr. Wilson Fox believed that the phthisical temperature was, as remarked by Dr. B. Sanderson, that of a chronic suppurative fever. In some cases of consolidation of the lung, when tuberculization of the lung is progressing somewhat rapidly, the temperature is comparatively low.

Dr. Douglas Powell thought it a pity to think of phthisis as one disease when there were so many varieties, some commencing insidiously, others, again, beginning with inflammatory catarrh.

Dr. C. R. Drysdale was glad to hear the author speak of the unity of the disease. It was a symptom that the confusionists of Niemeyer's school had had their day. Patients gained weight whether their temperature was high or low in many instances, when removed to the country and well fed. In a case of a Jew lately attacked with acute tuberculosis at his hospital, the temperature of 104° F. was the key to the nature of the disease, which at first was obscure. Jews not unfrequently died of phthisis. This he mentioned, because Dr. S. Gibbon had recently been reported as saying that these people were singularly exempt from the disease.

Dr. Henry Green asked if the rise of temperature in the third stage was due to the softening of the diseased portions, or to the occurrence of fresh tuberculization. He believed the latter to be the cause.

Mr. Herbert Page said the cause in the first stage resembled that seen in simple abscess, or in cases of amputation.

Dr. Leared asked whether any of the observations showed the condition of the temperature in the pre-tubercular stage.

Dr. Symes Thompson said the conclusion that quinine had the power of keeping down the temperature in pyrexia was unmistakable. Hence it appears that giving quinine in the day and food at night might alter the causes observed.

Dr. Curnow had observed that in some cases of phthisis with diabetes or albuminuria, there was no rise of temperature. The temperature of phthisis is that of hectic fever.

Supplemental Nerve Force.

A SURGEON of Lyons, M. E. Letafant, has demonstrated, in a work published in Paris, the following interesting propositions, which are recapitulated in the *Philadelphia Reporter*:—When a certain group of muscles, supplied by a particular nerve, are paralysed as the result of a section of that nerve, the motions properly belonging to this group of muscles are not in all cases wholly abrogated, adjacent muscles, supplied by unaffected nerves, being capable of accomplishing some part of the actions, even though feebly. Similarly, when a sensitive nerve is divided, there is not total loss of sensibility experienced throughout the entire region of its anatomical distribution,

the sensation being preserved, more or less feebly, either by means of the anastomoses of adjacent nerves, or by the conveyance of impressions indirectly to healthy neighbouring cutaneous papillæ.

Hospital for Animals.

THE BROWN INSTITUTION, in the Wandsworth Road, is a curious feature in London at present. Lame dogs, sick horses and donkeys form the out-door patients of this hospital. It was established by a gentleman who died twenty years ago, leaving over £20,000 for this purpose, bequeathed to the Chancellor, Vice-Chancellor, and Fellows of the University of London for the purpose of establishing and upholding an institution for investigating, studying, and without charge beyond immediate expenses, endeavouring to cure maladies, distempers, and injuries which any quadrupeds or birds useful to man may be found subject to. During 1873 there were about 7,000 animals, chiefly horses and donkeys, receiving treatment at the Brown Institute. Many of the horses, it was found, were the property of rich proprietors; so that the trustees have lately restricted the benefits of the charity to the poor. Hence, last year not more than 4,000 animals attended as out-patients. Of these 800 were dogs, and among these about twelve cases of rabies. The endowment of the charity gives only some £900 a year, which, after all expenses are paid, leaves nothing for the purchase of diseased or injured animals or their carcases for the promotion of science. Hence the whole results have been last year the delivery of some five lectures and the treatment of about fourteen animals daily. This is a very meagre result, and it seems that each animal treated costs the charity about 4s. 3d.

Ether.

DR. FURNEAUX JORDAN thinks that the profoundest anæsthesia of ether is not so deep as to prevent reflex muscular action from following an incision of the skin, and it is probably less profound than even ordinary degrees of chloroform narcotism. So that a patient, with ordinary care, can hardly be dangerously anæsthetised by ether. And yet this anæsthesia is enough for the vast majority of operations. The chief drawback of ether is that timid persons cannot easily administer it. It is not everyone who can resolutely pour out a large quantity of ether, resolutely and closely bind a towel round the mouth and nose, and disregard the most violent muscular contractions. But these are difficulties which an easily attainable knowledge and experience will surmount.

The Employment of Baths, &c., during the Menstrual Period.

DR. PRADIER has made a report upon the effect of baths on women whilst menstruating, from which the following conclusions are drawn in the *Tribune Médicale*, No 33, 1874.

1. According to several authorities, some strong medicines (such as bleeding, leeches, emetics, and purges) may be administered without inconvenience during menstruation.

2. Hydropathic treatment and sea-baths have been

given under the same circumstances for a long time without evil effects.

3rd. Several physicians do not dread to prescribe tepid baths in the same conditions.

4th. As to mineral baths, one of our brethren has permitted them in like circumstances for seven years past, without having seen the least accident occur.

5th. These facts have been ascertained and controlled by the reporter, who does not fear to affirm that hydropathic practices may be carried out without danger during the menstrual period, with exceptions which have regard in the first place to the impressionability of the subjects and to the psychical influences that ought always to be attended to.

Treatment of Obesity.

DR. RHILEBERT (*France Méd.*, Nov. 4, 1874), a fat gentleman himself, has just published a mode of treating polyseria which succeeded in his own case. He weighed when 20 no less than 342 pounds, and measured five feet round the waist. Dr. Shindler, of Marienbad, Bohemia, in July, 1869, gave him the following prescription: To get up at six; from half-past six to seven to drink three glasses of water from the Kreuzbrunn well. Breakfast on two soft-boiled eggs, a cup of tea, and small piece of bread, at eight. Vapour bath from nine till ten every second day for three weeks, then once a day, followed by a douche of cold water. At eleven o'clock, breakfast of two dishes of meat or fish, one of vegetables, a dessert without sugar, and half a bottle of wine. From twelve to six walking all day in the forest, as much as possible without fatigue. Dinner at six, on one dish of cold meat, half a bottle of wine, and piece of bread; then a walk. At eight p.m. shampooing with soap, and cold compresses to abdomen. Five pills, called "reduction pills," containing alkalies, to be taken. This treatment was well borne, and lasted six weeks. Thirst diminished, and was calmed, when excessive, by lemonade. In a week 12 lbs. were lost; in the next, 2 lbs.; in the third, 6 lbs.; in the fourth, 8 lbs.; at the end of fifth and sixth weeks, 7 lbs.; in all, 25 lbs., in six weeks. In November, having continued treatment at home, his weight was only 285 lbs.; and he now, Nov., 1874, weighs only 199 lbs., and has excellent health. The Marienbad water contains sulphate of soda, 4 grammes to the litre.

A Week's Deaths.

WE learn from the Registrar-General's returns that whooping-cough, small-pox, and scarlet fever were last week more or less fatally prevalent in Birmingham, and the deaths from scarlet fever and enteric fever excessive in Sheffield. The 1,650 deaths in London included 5 from small-pox, 8 from measles, 61 from scarlet fever, 7 from diphtheria, 39 from whooping-cough, 31 from different forms of fever, and 20 from diarrhoea. These 171 deaths were 83 below the average number in the last ten years. The 61 fatal cases of scarlet fever exceeded the number in the two preceding weeks, were 15 above the weekly average, and included 10 in the north, 15 in the east, and 23 in the south groups of districts; 4 were returned in St. George, Camberwell, and 3 in Clapham sub-districts. The Asylums District Hospitals contained 133 scarlet fever patients on

the 30th ult., against numbers declining steadily from 243 to 145 in the eight preceding weeks. The deaths from diphtheria showed a further decline from those returned in recent weeks. The deaths referred to small-pox were 5, against 5 and 6 in the two previous weeks; one was a case of chicken-pox in Stoke Newington, and the other 4 occurred in South London, including 1 in Clapham, 1 in Deptford, and 1 in the Small-pox Hospital at Stockwell. This small-pox hospital contained 18 patients on 29th ult., against 21 and 22 in the two preceding weeks. The 31 deaths from fever included 2 certified as typhus, 23 as enteric or typhoid fever, and 6 as simple continued fever; 2 fatal cases of enteric fever occurred both in Islington East and Mile End Old Town Eastern sub-districts, and 3 of fever (form undistinguished) in St. Peter, Walworth. The Asylum Districts Fever Hospitals at Homerton and Stockwell contained 70 fever patients on 30th ult., against 108 and 86 at the end of the two preceding weeks. The deaths referred to diseases of the respiratory organs, which in the four preceding weeks had declined, under the influence of the mild weather, from 897 to 468, further fell last week to 409, and were 4 below the average weekly number in the last ten years; 248 resulted from bronchitis, 104 from pneumonia, and 15 from asthma. Different forms of violence caused 64 deaths; 55 were the result of negligence or accident, including 16 from fractures and contusions, 8 from burns and scalds, 10 from drowning, and 16 of infants under one year of age from suffocation. The death of a servant in Charing Cross Hospital on 20th January resulted from hydrophobia; and that of an infant, aged 10 days, in Goodman's Fields, as referred to "hemorrhage from circumcision." Three of the deaths from fractures and contusions were caused by horses or vehicles in the streets; from this class of accident 62 cases of injury and maiming came under the notice of the police during the seven days. In the large public institutions 281 deaths were recorded, or 17 per cent. of the total deaths; of these 171 occurred in workhouse establishments, 94 in hospitals, and 16 in lunatic asylums.

Arsenic and Antimony.

As the result of numerous experiments on the action of arsenic and antimony upon the organism, Drs. Mayencon and Bergeret publish in *La France Médicale* the following conclusions:—

1. Arsenic is absorbed and diffused in the organism with very great promptness. Elimination through the urine takes place immediately.
2. Antimony is absorbed and diffused more slowly. Urinary elimination rarely begins on the first day.
3. Arsenic is eliminated simultaneously by the liver and kidneys, but more by the liver than by the kidneys.
4. Antimony is carried off in a much larger quantity by the liver than by the kidneys.

The Regius Professorship of Surgery in Dublin University.

It is announced that the Academic Council of the University will proceed to elect a Regius Professor of Surgery on the 3rd of March, and candidates are required to send in their names to the Provost of Trinity College before the 24th inst.

The candidates spoken of are Mr. Porter, Surgeon to the

Queen in Ireland, and Senior Surgeon to the Meath Hospital; Mr. Colles, Senior Surgeon to Steevens' Hospital; Mr. John Hamilton, Surgeon to the Richmond Hospital; and Mr. Wharton, Surgeon to the Meath Hospital. We will not be supposed to be expressing any opinion unfavourable to the other candidates if we say that Mr. Porter is generally considered likely to be the successful candidate. Mr. Colles' rank in the profession is of the highest, but his political views have never been those of the University, and, although the Regius Professorship is strictly an unpolitical appointment, still the choice of some of the Council may be more or less influenced by the consideration.

We believe we are correct in saying that Mr. Butcher will not be a candidate.

Upon this subject and the analogous question of the Irish surgical baronetcy which has been so long withheld from the profession the *Dublin Evening Mail* has thrown its influence into the scale in favour of the view which we have frequently advocated.

"It happens," says our contemporary, "at the present moment, that the death of Dr. Adams has opened a way for some slight recognition of public services and of the distinction conferred by the popular voice. For a considerable time it has been thought that a more direct mark of the favour of the Sovereign was as it were due to the profession of Surgery; that in short the medical baronetcy well bestowed by his Whig friends upon Sir Dominic Corrigan might happily be balanced by a similar dignity being conferred by the Conservatives upon some one of the eminent surgeons whom the public point to as deserving such a favour at their hands. It is not for us to decide upon claims, many of them very strong, in the public estimation; but we may mention one or two names which will be generally admitted to bring with them their own recommendation to the Government and the University. Mr. Colles, the Senior Surgeon to Dr. Steevens' Hospital, well supports, in the opinion of his brethren and of the public, the great reputation of his father, which contributed so much in the last generation to the establishment of the Irish School of Surgery as one of the very foremost in Europe. Mr. Porter, as Surgeon to the Meath Hospital, stands at the highest point alongside of Mr. Colles, both eminent representatives of Irish surgical ability and skill, not inferior to their respective fathers. With these gentlemen before us there could be no danger of mistake in the distribution of the favours at the disposal of the patrons to whom we have referred. Mr. Porter has been often mentioned in conjunction with Mr. Adams as a fitting recipient of the special dignity to which it is felt that the profession has a just claim: he now stands by himself, and is indicated for further distinction by his being also Surgeon-in-Ordinary to the Queen. No more efficient Regius Professor of Surgery could be found for the University than Dr. Colles."

We are glad to see that the expression of our opinion upon the justice of granting a titular distinction to the Irish surgical profession, and upon the recipient of the honour, if it should be granted, has met with corroboration from the most independent and influential Conservative journal in Ireland.

We hold still our formerly expressed feeling that the

continued withholding of the baronetcy which was vacated by the death of Sir Philip Crampton is an unmerited slight upon the profession, and that Mr. Porter is indicated in the public mind as *facile* the surgeon upon whom such honour, if granted, should fall.

The Charity Voting Reform Association.

THIS Association, which has for its object a modification of the system of electing candidates to charitable institutions, has published a portion of the "Correspondence" which has taken place with certain institutions and individuals in reference to the system of canvassing and voting. The correspondence is exceedingly interesting, and in some measure curious, and is well worth perusal. It includes letters on the Royal Medical Benevolent College, and the action lately taken by the Council to provide a remedy for evils which only serve to increase expense, harass and waste the time of the candidates and their friends, while it goes far towards converting them into begging-letter writers. The resolution passed by the Council will in no wise correct the evils complained of, as it only went to the placing of the names of subscribers that object to the present system "on a separate list." In what way this is expected to help the poor widow who writes to the Secretary of the Charity Voting Reform Association, "But for the goodness of Dr. Jonson I could never have succeeded, though I spent more than £60 in the canvass, and am still paying it off to friends who lent me the money," it is impossible to conceive. The only possible remedy for existing evils is, "that all cases should be investigated and classified, and that they should be admitted to the benefits of the charity according to the strength and urgency of their respective claims."

We agree with the various correspondents of the Charity Voting Reform Association, that the London charity voting system, as at present conducted, is simply an abomination. It is, therefore, not to be wondered at that Lord Overstone writes to say: "I have long since discontinued further contributions to societies which persist in the voting system;" and Lady Stanley and the Dean of Westminster: "We have groaned over the miserable system;" the Earl of Shaftesbury: "The poor and deserving cases, if unsupported by money and friends, have positively little or no hope of success;" and Miss Florence Nightingale: "My experience of it induces me to describe it (the voting system) as the best means for electing the least eligible, or, at any rate, the system for preventing the discovery of the most eligible," and further: "From an experience of thirty years I do so deeply know the crying evils and injuries done by the canvassing and voting system to those intended to be benefited, and not only those, but the miserable waste of time (by the canvassers) which might be usefully directly employed in wisely serving the sufferers, that I cannot but wish God speed to every effort made to substitute real and direct charitable effort for this infinitely distorted caricature of it." This correspondence may be obtained at the Office of the Association, 30 Charing Cross.

The Brain in Typhoid.

DR. W. H. DAY read a paper on "The Cerebral Complications of Typhoid Fever in Children." He said that

the frequency of diseases of the nervous system in early life, and the dangers which attend their course when they occur as the sequel of disturbance in the vascular system, give them an importance which cannot be over-estimated, and invite our attention to the grave consequences that might follow a false or imperfect diagnosis. The nervous system derives its strength and vigour from a due supply of healthy blood, and if this in any way changed or disorganised by the fever process, it becomes excited, depressed, or in some way unstrung. Thus it is that independent of the febrile condition, morbid sensations, nervous, prostration and those mental phenomena of which we daily see the effect rather than the cause are of such common occurrence. The author cited two cases of cerebral complication occurring in the course of typhoid in which the post-mortem appearances gave a perfectly healthy state of the brain and its membranes. He related two other cases in which he believed the inflammatory process played some part in the changes that were observed in the brain—changes independent of the tubercular cachexia and where no such deposit could be found in any organ of the body. It was impossible to enumerate any symptoms as diagnostic of the degree of cerebral congestion that might be present in any given case. The state of the brain and its membranes bore no approximate relation to the symptoms. The author considered that meningitis uncomplicated with the tubercular cachexia occurred now and then in typhoid fever in rare and exceptional cases. Setting aside the injurious effect which the circulation of poisoned blood at an elevated temperature must have on the nervous centres, there seems no satisfactory reason why the cerebral changes should be restricted to congestion of the vessels, or simple vascularity of the membranes.

The author endorsed the statement of other observers that we cannot, in certain obscure cases, separate a form of typhoid in young children characterised by a distinctly remittent type from cerebral meningitis. If the symptoms are mixed up together in various degrees, the diagnosis between the two affections is often impossible. There were few greater or more perplexing difficulties in the practice of medicine. The author commented on the dangers of hasty induction and rash conclusions, and pointed out the risk of setting down the vomiting and cerebral symptoms to the typhoid state, whilst the brain might have been slowly and imperceptibly going wrong, and was perhaps the primary source of trouble.

The Potato Panic.

BELGIUM is about to follow the example of her neighbour in the East and to pass a stringent law with regard to the prohibition of imported potatoes "de provenance suspecte." The special committee appointed by the Chamber to examine into the question and report upon the proposed law have pronounced unanimously in favour of the latter, and so pressing do they consider the matter that they urge the Legislature to append a clause bringing the Act into immediate operation. M. J. Serstevens, the spokesman of the committee, also hinted at the expediency of other countries in Europe adopting similar and simultaneous action on the subject; and, in truth, if the facts which the reports contain are not gross exaggerations, it concerns England and Ireland very vitally not to treat the matter with

neglect. According to information gathered from various sources, and especially from the numerous agricultural journals in Belgium, the vicious propensities of the dreaded insect are only equalled by its capabilities for mischief. In six years its ravages spread for a distance of 360 miles across America, and it would therefore not be a long time in overrunning the Low Countries were it once domiciled therein. The reproductive powers of the devastator are such that a single couple are estimated as likely to bring into the world in one favourable summer some sixty millions of voracious children. Nor is this amazing fertility accompanied, according to the usual law of Nature, by any lack of vitality on the part of the parents or their progeny. The hardiness of the insect is, on the contrary, remarkable, as may be imagined from the fact that five of them enclosed in a letter and despatched by post from Canada to England, arrived at their destination "in perfect health." Another vivacious specimen was kept without food by a professor of Wisconsin for six weeks, and, so far from being aggrieved by the barbarous conduct of the learned men, testified its perfect indifference to his want of gallantry by laying in the meantime some 1,200 eggs. The Belgian committee, besides thus enumerating the prowess and feats of the doryphora, proceed to estimate the effect likely to be produced by its acclimatisation on the farms of the country. The number of acres devoted on an average to the cultivation of potatoes in Belgium is about 428,000. Upon each of these acres an average of 10,000 lbs. is produced, so that the loss to be apprehended if the formidable insect were to establish itself in full sovereignty would amount to no less than 4,600,000 lbs. Decidedly the Commission is not guilty of pessimism when it avers that an "alimentary crisis" is on the cards.

The Seamen's Hospital.

THE fifty-fourth annual report of the Committee of Management of the Seamen's Hospital (late Dreadnought) Society, Greenwich, to be presented at the meeting of governors, states that during the past year relief has been afforded to a greater number of seamen than in any previous year; 2,058 patients were admitted, and, in addition, 1,509 received advice and medicine gratuitously. Whilst the annual expenditure amounted to £11,227, as against £8,968 in the previous year, the income decreased from £9,936 to £8,209. Considering the national character of the work undertaken by the charity, the committee urge that increased contributions should be made by the public.

Permanence of Vital Power.

IN clearing away the refuse from the ancient silver mines of Larium, in Greece, a large number of seeds of a papaveracea of the *Glauicum* genus were found, which must have been buried there for at least fifteen hundred years. Exposed to the beneficent influence of the sun's rays, they rapidly took root, flourished, budded, and blossomed, their yellow corollas being beautiful in the extreme. This interesting flower, unknown to modern science, is particularly and frequently described in the writings of Pliny and Dioscorides, and is thus again resuscitated, after having disappeared from the surface of the globe for more than fifteen centuries.

New Books for the Month in Medicine, Surgery, and Science.

Announcement.

A Short Manual of Heat. By Rev. A. Irving, B.A.

Vegetable Tissues for the Microscope.

DR. W. G. HARRISON, on the part of the Maryland Academy of Sciences, reports a new mode of preparing fresh vegetable tissues. This process is briefly described as follows: First, the specimen, say a leaf, is decolourised, by soaking in a solution of chlorinate of soda. Second, the soda remaining in the leaf is removed by washing in water. Third, the leaf is then washed, first in dilute alcohol, increasing its strength gradually until the water is removed. Fourth, the specimen is submitted to one of the staining fluids known to the art; aniline blue is generally used, and was selected for the slide shown by the doctor. If too much colour is given it can be partially removed by alcohol. Fifth, a solution of oil of cloves is used to remove the alcohol. Sixth, the leaf, being properly prepared, is mounted with Canada balsam.

Tolerance of Bee Stings.

THE *Philadelphia Reporter*, remarking on the statement by an English journal devoted to apiculture that after one has received about twenty stings from bees, within about a month, a tolerance is established to such a degree that no subsequent swelling and hardly any pain is caused by the sting, says that a similar inoculation unquestionably follows mosquito bites.

Pharmacy Legislation for Ireland.

MR. ERRINGTON, who obtained the appointment of the Select Committee last year, has elicited from the Chief Secretary for Ireland the announcement that he is about to bring in a bill this session for the regulation of pharmacy in Ireland. We are glad to have read this statement, because it promises some sort of definite settlement of a long-mooted question, and something like a reform in the state of chaos in which the Irish Apothecaries' Company has plunged pharmaceutical interests.

There are before the Chief Secretary, our readers will remember, three alternative proposals: *Firstly*, the bill of "the Hall," which aims at maintaining the *status quo*—*is*, perpetuating the sham medical degree of the Hall—*by* establishing a minor grade of dispensers on a purely pharmaceutical examination. *Secondly*, the bill of the College of Physicians, which wishes to import the English

Pharmaceutical Society *in globo*. *Thirdly*, the recommendation of the Select Committee that an Irish Pharmaceutical Society should be formed and entrusted with the control of education and examination. We suspect the Chief Secretary of favouring the College of Physicians' scheme, to which we have declared ourselves hostile; but we believe that even this alternative will be preferable to the farce still played daily to empty benches by the "stock" actors of the Apothecaries' Hall.

The Fly in the Pot of Ointment.

OUT of the £8000 a-year which the British Medical Association receives for its income it has granted for scientific purposes—£165. The application of this stimulus to the motor system of the scientific world will not fail to produce an increased energy in investigation. For instance, one gentleman is subsidised for investigations in search of an "antidote for chloroform" with a grant of £5. Each of the gentlemen who contributed a fraction of a halfpenny to the cause of science must feel that they are public benefactors.

The late Chemical Appointment in Dublin University.

THE appointment of Dr. Emerson Reynolds to the Professorship of Chemistry in Dublin University in the room of Dr. Apjohn is regarded by the scientific circle of Ireland with unqualified approval. The University has been happy in securing as the successor of Dr. Apjohn, who was in his day the most advanced chemist in the United Kingdom, a gentleman who has forced his way into the highest public estimation by real sterling scientific work, and Dr. Reynolds may congratulate himself on having attained a just reward of his perseverance and industry. The son of an unassuming medical practitioner in a suburb of Dublin, he owes nothing of his advancement either to interest or subserviency.

Dr. Apjohn cannot vacate his chair without an expression on our part of the sense which the medical profession and scientific men in Ireland entertain as to his great services. He was, since the death of Davy, the chemist of his day, and, moreover, a man of thorough honesty and independence of character. He was (with perhaps the exception of Geoghegan) the most lucid lecturer and skilful experimentalist of his day. Both he and Reynolds are chemists, not mere chemical traders—a distinction which our readers will readily comprehend.

The promotion of Dr. Reynolds vacates the Professorship and the Directorship of Minerals at the Royal Dublin Society, and the Professorship at the Royal College of Surgeons. To the latter office it is probable that Dr. Cameron, the city analyst, will succeed, in which case the Lectureship at the Ledwich School will be a subject of competition.

Belfast Corporatorism.

A MEMORIAL has been forwarded to the Local Government Board, signed by 19 medical gentlemen in Belfast, complaining of the Town Council's apathy for twenty years, after obtaining special Parliamentary powers to abate the Blackstaff and Pound river nuisances. The memorial requests the Board's interference to compel the Council, as local sanitary authority, to abate the nuisance.

Armagh District Lunatic Asylum.

THE Board of Governors have unanimously resolved to expend £10,000 in enlarging and improving this institution. The Government is to advance the money, free of interest.

The Anti-Vivisectionists.

THE Society for the Prevention of Cruelty to Animals is making a great hubbub about the supposed cruelties of vivisection in our medical schools, and it appears by a circular issued to the hospital authorities a special committee has been appointed to watch over the doings of the teachers of physiology. We venture to suggest to this vigilance committee a wider and more useful field in which to display their humanitarian interest on behalf of suffering animals—namely, in trying to put down the useless and cruel sport of shooting tame pigeons, and the very needless cruelties of the hunting-field. It is quite possible that a Royal Society for the Prevention of Cruelty to Animals may in time succeed in convincing gentlemen that the hunting harmless hares and half-tamed foxes to death is attended with a good deal of cruelty. At all events, if success attend the Society's efforts in this direction the public will be spared the pain and scandal attached to such deaths in the hunting-field as that of the Rev. C. Wilkinson, a clergyman of 79 years of age, who, it appears from the newspapers, was thrown from his horse while following the Bramham Moor hounds and killed on the spot. It is perfectly shocking to think that an aged clergyman should have met his death in the pursuit of a cruel sport.

The Hunterian Oration.

A VERY crowded audience assembled at the Royal College of Surgeons of England on Saturday to listen to the oration by Mr. F. Le Gros Clark, F.R.S., President of the College. Of course, it is impossible to say anything new of the illustrious anatomist whose memory these annual orations are intended to perpetuate; nor did the orator attempt anything sensational, or pretend to aught which had not been said a dozen times by his predecessors; he wisely contented himself with a plain historical sketch, passing a well-merited tribute to the memories of the late Professor Partridge, Mr. Swan, Sir James Ranald Martin, and Mr. Kiernan. He also expressed his entire concurrence with the proposed arrangement for an amalgamation between the medical corporate bodies, with a view to having one common portal by which all candidates may obtain a qualification to practise.

The Hunterian Dinner at Willis's Rooms in the evening of the same day was well attended. Amongst those present were the Lord Chief Justice of England; Lord Coleridge, Lord Chief Justice of the Common Pleas; the Dean of Westminster; Sir George Burrows, Bart., F.R.S., President of the Royal College of Physicians; Dr. Acland, F.R.S., President of the Medical Council; Dr. Macnamara, of Dublin; Dr. Fayer; Sir William Jenner, Bart.; Sir William Fergusson, Bart.; Sir James Paget, F.R.S.; Dr. Carpenter, F.R.S.; Professors Paget and Humphry, of Cambridge; Professor Huxley, F.R.S.; Mr. Cæsar Hawkins, F.R.S., &c.

We learn that Mr. Effingham M'Dowel, son of Dr. M'Dowel, Professor of Anatomy in the University of Dublin, has achieved at the Commencements which have just been held a very remarkable distinction. Mr. M'Dowel received three medical and surgical qualifications—viz., the M.B., M.D., and M.Ch. On referring to the returns furnished and posted by the Medical Registrar, we find that Mr. M'Dowel obtained the rare distinction of gaining first place in the examination for medical degrees, scoring 66 per cent., and first place in the examination for surgical degrees, with 84½ per cent. In accordance with a regulation of the Board, and as a recognition of merit, the surgical degree (M.Ch.) was conferred on Mr. M'Dowel. "St pendis condonatis." This, we believe, is only the third or fourth time that any one candidate has gained such a distinction, what in Oxford and Cambridge language would be called a "double first." We are reminded that Mr. M'Dowel had previously distinguished himself in his arts course as a gold medalist and senior moderator.

In a work entitled "Statistical Researches as to the Causation of Tertiary Syphilis," by Dr. Louis Jullien, published in 1874 (Paris, Masson), the author asks, Should mercury be administered as soon as the primary sore is seen? or is it better, on the contrary, not to commence its employment until general accidents appear? Such was one of the questions of the programme proposed at the Congrès Médical of Lyons in 1872.

Finding that the members of the Congress had only in reality studied secondary symptoms, and that the true question had remained in the dark, Dr. Louis Jullien renewed this study, and investigated what was the influence of mercury on the progress of syphilis. The author studies the first, evolution of natural syphilis, that is to say, syphilis which is submitted to no treatment; (2) syphilis treated with mercury from the first, that is, at the commencement of the primary accident; (3) lastly, the evolution of syphilis treated with mercury from the secondary epoch, that is to say, those cases of syphilis where the mercury has been prescribed in the course of the secondary accidents only.

Dr. Jullien bases his conclusion on 237 cases, from the analysis of which he derives some of the following conclusions: (1) Persons with syphilis who take mercury in the commencement of the secondary period constitute the great majority of the tertiary accidents we meet with, whether in hospitals or in private practice; after these come in order of frequency the cases of syphilis left to nature, and then those treated by the specific at the commencement of the sore. (2) Those cases of syphilis submitted at once to mercury, and those which are most slowly evolved; then come cases of natural syphilis and then cases of syphilis where mercury is given as soon as secondaries appear. (3) The tertiary lesions of the testicle and nervous system are the almost sole appanage of mercurial treatment. (4) Lastly, in his last and principal conclusion, the author thus expresses himself: "If we had to arrange in a general manner our three series according to their benignity, we should adopt the following order: (1) natural syphilis; (2) syphilis mercurialised from the first; (3) syphilis mercurialised from appearance of secondary symptoms."

In offering the Metropolitan Asylums Board an alternative site for their new Fever Hospital, the Hampstead Heath Defence Committees have thrown on the members of the Board a serious responsibility. Their present site is at the head of the drainage system of a valley which runs through the densest parts of London, and it is by the drainage typhoid fever spreads: It is, too, on the most pleasant of the Northern heights, and at the very gateway of Hampstead Heath. The new site in Mill Lane is on another slope of the hill, far more open and airy than the present site. It has a southern aspect; and while it is, in some respects, more accessible from that large portion of London which most needs the accommodation such an hospital offers, it is so nearly isolated as to reduce the danger of infection to a minimum. Dr. Murchison reports strongly in its favour. It is larger than the present site by half an acre; it is about half as costly; it is approached by three roads instead of one; and it is clear away from the holiday multitudes who frequent the Heath, and from the schools and private dwellings of the favourite suburb. Dr. Murchison states that there is no sanitary objection to the new site except that the soil is clay, but that applies equally to the site of the existing hospitals. In position it stands at the apex of an equilateral triangle, of which the base is formed by a line connecting the hospitals at Homerton and Stockwell; it therefore, says Dr. Murchison, "fulfils one of the objects which the Asylums Board had in view after its first organisation in 1867, viz., 'to reduce to a minimum the distance which patients from all parts of the district will have to be carried to reach the hospitals.'" But the one recommendation which ought to outweigh all others is that, with equal advantages to the hospital and its patients, it is free from the enormous disadvantages to the public which the other site entails. It is not creditable to the administrative ability of the Metropolitan Asylums Board that a proposal to place a Fever Hospital on the spot of which the people of Hampstead complain should have been entertained; to adhere to it against almost universal protests when a site equally advantageous is offered would be worse than a blunder.

The next evening meeting of the Pharmaceutical Society of Great Britain will be held on Wednesday evening, March 3, 1875, at eight o'clock.

DR. R. J. LEE will lecture "On Puerperal Fever" at the Royal College of Physicians of London on February 19th, 24th, and 26th, at five o'clock.

THE students of University College Hospital gained a hollow victory in the football match last week over the London Hospital. The victory of Guy's over the Middlesex Hospital students was equally decisive.

It appears from the Registrar-General's return, that during last week there were 1,552 deaths registered in the metropolis, representing 24 per 1000 of population per annum, whilst the average of English towns generally was 26 per 1000. It was 21 in Edinburgh, 31 in Dublin, and 32 in Glasgow. The maximum in English towns was 35, at Nottingham, and the minimum 20, at Bristol.

WE understand that a new hospital is about to be erected at Mansfield Woodhouse, Nottinghamshire. Dr. Waring Curran has promised £100 towards the fund, and it is expected that His Grace the Duke of Portland will give the site.

THE Statistical Society of England has announced that the title of the essay to which the "Howard" Medal will be awarded in November, 1875, is "The State of the Dwellings of the Poor in the Rural Districts of England, with special regard to the Improvements that have taken place since the middle of the 18th century; and their Influence on the Health and Morals of the Inmates."

THE Audit Committee of the London Hospital Saturday Fund have presented their report, showing gross receipts of £6,300, less £1,400 expenses. It was decided to distribute £4,500, and to carry forward the balance, £400, to this year's collection. Two-thirds of the amount was allotted to hospitals, and the other third to dispensaries.

Literature.

DIGEST OF THE SANITARY LAWS IN FORCE IN IRELAND. (a)

IN the Supplements issued from time to time with the MEDICAL PRESS we have presented our readers with this valuable Digest of the "Sanitary Laws in Force in Ireland." The concluding portions of Mr. Wodsworth's pamphlet appeared in our issue of the 3rd instant, and if we have not formally recorded our appreciation of this very valuable digest of the sanitary laws, we felt that in transferring its contents *in extenso* to the pages of the MEDICAL PRESS we tacitly offered the highest compliment that we could pay to its author. In a recent issue we remarked upon the importance of medical officers making themselves acquainted with the duties they would be called upon to discharge in connection with the Public Health Bill. We might, with great propriety, have added that of the knowledge which we then urged them to acquire, no branch was of greater practical importance than that which would make them acquainted with the legal enactments already in force on subjects connected with sanitary science. This pamphlet conveys exactly that knowledge which constitutes a power in the hands of a medical officer of health. Within the limits of thirty-six pages the accomplished assistant-secretary of the Local Government Board has presented a digest of the various acts bearing upon the public health, and now in force. Few persons are aware of the prodigious amount of labour which such a compilation represents, and, on behalf of the medical officers of health throughout the country, we tender our thanks to Mr. Wodsworth for placing within the reach of the profession a valuable synopsis of the legal enactments bearing upon their important duties.

In our issue of the 3rd instant, having in mind an expression which fell from the lips of the Earl of Derby to the effect that, for the masses, sanitary instruction was, if possible, more important than sanitary legislation, we draw the attention of the Local Government Board to a valuable paper upon sanitary precautions against fever, and to a collection of sanitary rhymes, both calculated to instruct the uneducated class in the first principles of

(a) "Digest of the Sanitary Laws in Force in Ireland, in connection with the Public Health (Ireland) Act, 1874." By W. D. Wodsworth, Esq., Assistant-Secretary, Local Government Board. Dublin: A. Thom, for H.M. Stationery Office.

sanitary science. In recommending those papers to the Local Government Board for their adoption we unconsciously paid a compliment to that department, for we have since been informed that the papers to which we referred with sincere expressions of appreciation emanated from the Local Government Board. We can now only add the expression of a hope that they may be largely distributed by dispensary medical officers throughout the country. Wherever the principles laid down in those two papers are brought home to the understanding of the classes who seek dispensary relief, the sanitary executive officers will find the task of carrying out the provisions of the Public Health Act deprived of half its difficulty.

NATURE AND DESTRUCTIVE VARIETIES OF LUNG DISEASE. (a)

THE divergency of opinion among the profession on the subject of the pathology of tubercle is very greatly to be regretted. Not only is the origin of tubercle itself diversely explained, but pathological changes, the result both of chronic and acute disease, have been confounded with tubercle, and alterations purely incidental mixed up with tubercle, its origin regarded. If we adopt Dr. MacCormac's view, that tubercle is simply the unexcreted unoxidised carbonaceous waste, and there seems no fair way of evading his most important conclusions, tubercle in whatever stage should be carefully discriminated from the products of inflammation, whether acute or chronic. Nothing indeed is less uncommon than the supervention of pleuritis or pneumonia in lungs already infested with tubercles, while chronic bronchitis, though there prove many exceptions, is one of the most common associates of tubercle, at least pulmonary tubercle, imaginable. Dr. MacCormac has shown on evidence from his own experience, as well as fortified by the observations of Louis and others, that Drs. Fox and Sanderson's conclusions as to the origin of tubercle in inflammation are quite untenable. Tubercle may be preceded, attended, or followed by inflammation, but this concurrence, when it ensues, is purely accidental, and cannot for a moment, rightly at least, be looked upon as subsisting in the relation of cause and effect. There is no such thing as what Dr. Williams calls "artificial tuberculation," and tubercle as the result of "inoculation" is a purely imaginary condition. Tubercle from or by "infection" is simply pathology run mad, and has no existence in nature whatsoever.

These few remarks premised, we may proceed to Mr. Alcock's interesting diagram, showing the varying range of the heightened temperature in phthisis. He cites from Dr. Ringer what would be an important fact, if only we could verify it, that a "persistent elevation of temperature is the invariable precursor of tubercle in any organ." But how, in the name of goodness, are we to ascertain when tubercle is imminent in any organ. We do not, in fact, know, and the inference, therefore, we must perforce characterise as supposition. Mr. Alcock's remarks touching the prevalence of tubercular phthisis among our soldiers in India are of very great moment. Instead, however, of ascribing it to the "slowly acting deleterious influence of the Indian climate" (see p. 9 of Mr. Alcock's able *brochure*), we would refer it unhesitatingly to the evil barrack atmosphere, and sleeping places charged with an already respired atmosphere. Indeed, Mr. Alcock himself (*vide* p. 11) admits fully the deadly influence of overcrowding in regard of the production of tubercular phthisis, and at p. 12 and after, cites the most conclusive corroborative instances and illustrations from Parkes, Maclean, Petteukofer, and his own prior experience. If every surgeon only would do as Mr. Alcock has done, and record the results of his experience beyond seas, it would lead to results the most valuable, and greatly tend to lessen the risks and casualties to which foreign military service is now undoubtedly liable.

(a) Reprint of an article from the last Report of the Army Medical Department. By Surgeon-Major Nathaniel Alcock.

THE ENGLISH LOCAL GOVERNMENT DIRECTORY FOR 1875. (a)

THIS is a very useful hand-book for the table of the sanitary medical officer, and for all who need information about the Local Government Board, the Poor-law Board, Asylums Board, Sick Asylums Board, Lunacy, the Registrar-General's Department, &c. Complete lists of public analysts, rural and urban authorities, are also classified conveniently for reference; whilst at the end an appendix of the various forms are so arranged that one may see at a glance the requirements for the several official posts held under the Local Government Board.

BRAITHWAITE.

WE have so often had occasion to compliment the editors of the "Retrospect" that we need scarcely do more than announce the punctual appearance of the new volume. The oldest half-yearly is now the only one, and will therefore, we should hope, become still more widely read. The synopsis is a most valuable feature, and is very carefully compiled. The "Retrospect" ought to be found in every medical library.

OUTLINES OF THE SCIENCE AND PRACTICE OF MEDICINE.

THE great success of Dr. Aitken's larger work is well known to both students and practitioners, many of whom will have heard with delight that the author has published a smaller text-book, which may be regarded as a complete abstract of his *magnum opus*. We have looked through this smaller text-book with considerable interest, and have examined several of the articles. Although therefore, we have not read every chapter of the work, we feel entitled to recommend it to students, who will find it serve as an excellent medical manual. It will also be of special use to those who have carefully read the learned author's "Science and Practice of Medicine," and who desire to refresh their memories before submitting themselves to the examining boards. The "Outlines" may also be advantageously used as an introduction to the larger work, but for this purpose its conciseness may render it less popular. For practitioners we should decidedly recommend the large 2 vol. work, the completeness of which renders it of great value for reference, whilst the small text-book necessarily avoids controverted questions, and is dogmatic in its teachings.

This is just what a student needs, while a practitioner ought to be able to appreciate differences of opinion and compare them with advantage to himself.

Correspondence.

THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The Rev. Dr. Houghton, in no measured terms, has inveighed against me for daring to "attack" him by asserting, that the statement made by him was "entirely incorrect," namely, that "the proposal at the time (1867) to create a new order of Member was a change of front rendered necessary by the action of the British Medical Association in favour of the 'one portal' system." With the view of proving that he was not guilty of "falsehood and stupidity," and also that I was "a fool" (I quote Dr. Houghton's own words), he has produced a letter from Dr. Waters, of Chester, which contains the following paragraph: "When the Association

(a) "The English Local Government Directory for 1875." London: Knight and Co.

met in Dublin (1867) the Government had charge of a Bill embodying the 'one portal' system."

Dr. Haughton says, with respect to this letter, that it "fully disposes of Dr. Atthill's wild assertion that I stated what 'was incorrect' and 'impossible,' for my statement was pure and simple fact." And so it does, if it be true; but I assert that it is not true, and that Dr. Haughton's statement consequently is not a "fact."

With reference to this assertion of Dr. Waters, I require him and Dr. Haughton to produce a copy of the Bill referred to, or at least a reference to it in the journals of the day, and also to state by whom the Bill was drawn up and placed "in charge of the Government."

This is, you will admit, a very reasonable demand, and if they fail to comply with it, I have a right to ask your readers to believe, as I do, that no Bill embodying such a principle was then (1867) "in charge of the Government."

It is very remarkable that instead of quoting the clause of the Bill, which, "being in charge of the Government," must have been made public, Dr. Haughton should think it necessary to obtain, for the purpose of refuting me, a letter from a private friend; but any surprise at his adopting this course will be dissipated when I state that in the only Bill relative to medical reform, of which there is any record in existence, of having been at the date of the Dublin meeting (1867) brought under the notice, much less in charge of the Government, there is not any reference, direct or indirect, to the "one portal" system.

To what Bill, then, can Dr. Waters refer. He says: "At Dublin the Association decided that 'direct representation' of the profession in the General Medical Council must be embodied in the measure." Let your readers refer to the proceedings of the Association in Dublin, as reported in the *British Medical Journal* for August 10, 1867, page 112, and they will find that the Bill referred to, and which the Association pledged itself to support, was "the proposed Bill of the General Medical Council for the Amendment of the Medical Acts." This Bill was brought forward by the General Medical Council in 1866, referred back to them by Government, and again brought forward, slightly modified, in 1867. That Bill lies before me now, and I assert that it does not contain the most trifling reference to "the one portal system." Such of your readers as desire to satisfy themselves on the point, can do so by referring to the number of the *MEDICAL PRESS AND CIRCULAR* for May 23, 1866, or to the *Lancet*, vol. i., 1867, page 164. An abstract of the "principal clauses" will also be found in the number of the *British Medical Journal* for May 25, 1867.

The Bill refers solely to—

1. The registration of persons holding diplomas from colonial or foreign universities or colleges—to the registration of certain degrees in surgery obtainable from British universities; 2. The repeal of clause 40 of the Medical Act (1858); and 3. The punishing of persons assuming medical titles without being registered.

The meeting pledged itself to support this Bill, and no other. Further, no reference whatever was made at the Dublin meeting, either in the Report of Council, or in the debate which subsequently ensued, to the "one portal system" (see *British Medical Journal* for August 10th and 17th, 1867).

I distinctly affirm that Dr. Waters' statement that "when the Association met in Dublin (1867) the Government had charge of a Bill embodying the 'one portal' system" is "entirely incorrect."

Dr. Haughton says that my "character for wisdom and infallibility will not stand higher after my attack on him." As to infallibility, I was under the impression that but one mortal man laid claim to that attribute, and that even his claim was disputed by some; and I leave it to my professional brethren to decide as to the wisdom or otherwise of the course I have adopted in openly and fearlessly advocating what I believe to be for the good of the College to which I have the honour to belong, and as openly pointing out what I believe to be wrong or "incorrect." But be their judgment what it may on this point, I think it probable that the wisdom and discretion of the Rev. Dr. Haughton will not be highly esteemed by your readers when they find that to support a statement in itself "entirely incorrect" he makes use of terms such as are to be found in his published correspondence, and finally produces a letter of so suspicious a character as that signed by Dr. Waters; indeed, I believe not a few will agree with me, that, to quote the words of an ecclesiastic of even greater eminence than Dr. Haughton himself, he

"will have to purify both his mode of thinking and writing" before he is in a position to lay claim to a character for wisdom, or be entitled to the confidence of your readers.

Your obedient servant,

11 Upper Merriam Street,
1st February, 1875.

JOMBE ATTHILL.

Having read with some surprise the statement of Dr. Waters as to the inception of the "one portal" idea in a practical legislative shape, we examined the files of our journal for the years 1865 to 1868, and failed to find any corroboration of the statement. We therefore asked Dr. Waters to favour us with a reference to the Bill, of that date, in which the one portal system was to be found, or to any documentary evidence of its existence. We received the following reply:—

DEAR SIR,—Among the chief points of medical reform which it has been the duty of the Committee of the British Medical Association to contend for have been the direct representation of the profession in the General Medical Council and the establishment of the "one portal."

In 1867, when the Association met in Dublin, the Committee were of opinion that the principle of the "one portal" was safe in the hands of the Government, and that the important point for the Association to struggle for was that of "direct representation," and that alone. In my hurriedly written letter to Dr. Haughton I should have said the Committee believed that the Government had charge of "the principle" of the one portal, and not of "the Bill."

I am sorry to find myself involved in an angry discussion where all parties are, as I believe, desirous of stating the truth.

I remain, yours faithfully,

EDWARD WATERS.

14 Nicholas Street, Chester,
February 8, 1875.

[We are bound to say that we have no evidence before us that in the year 1867 the "one portal" system was "safe in the hands of Government."—ED. M. P. & C.]

VIVISECTION AT NORWICH.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is really sad to find such efforts now being made to extend the horrors of vivisection in this country, and also to witness the attempts of interested parties to bully down that worthy and justly-respected man, Sir William Fergusson. Sir William has a perfect right to hold his opinions on this as on other subjects, and his opinions are at least as reliable, if not much more so, than those of his medical brethren who may happen to entertain opposite views.

It is scarcely to be doubted but that the vast majority of medical men condemn vivisection as unnecessary and cruel; and many would, like Sir William Fergusson, sacrifice time, or incur serious personal inconvenience and loss, in their noble endeavours to prevent the repetition of such demoralising exhibitions as lately disgraced the proceedings of the British Medical Association during their meetings in Norwich.

Sir William Fergusson's name will shine with still brighter lustre for the honourable position he has taken in this matter, and will not be in the least tarnished by the vilifications of anonymous writers. And why, it may be asked, do the writers of these productions withhold their names? Simply because vivisection, like all other cruel *men*, are invariably cowards. They are such *men* as would very prudently shrink from attacking a tiger unless it was chained, but have sufficient courage to slowly torture bound and helpless dogs, cats, &c. Unfortunately, there are still *men* (if the term should be applied to such monsters) who delight to inflict pain, and can even gloat over the writhings and agonies of defenceless creatures.

Dr. Magnan has already received from the Academie des Sciences £100 as a reward for his performances; still, some anonymous writers think his medical brethren here should

make a presentation also. Doubtless this would be very acceptable to Dr. M., who, whilst jingling the sovereigns in his pocket, could chuckle over the credulity of the British Medical Association, and might manage to have some fresh interesting discovery ready at each future annual meeting in this country, of course taking philosophic care on every such occasion to be again safely out of reach before the Royal Society for the Prevention of Cruelty to Animals could catch him.

I am, Sir, yours respectfully,

WM. F. C. S. CORRY.

Belfast.

[We print this letter as a specimen of the length to which a correspondent may be led, by feelings which are in themselves worthy, to attribute the worst motives and make use of violent language. We have every sympathy with Sir William Fergusson's views, and an utter abhorrence of unnecessary cruelty to animals; but we do not think that the interests of the human race, which have indubitably been in certain cases advanced by vivisectional experiments, should be sacrificed to an excess of tenderness for cats and dogs. The cause of humanity will not be served by calling those who make use of vivisection by such names as "coward" and "monster," or by suggesting venal motives.—ED. M. P. & C.]

THE ARMY AND NAVY AND THE CONTAGIOUS DISEASES ACTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your recent article on the above subject induces me to ask space for a few words. It has always appeared to me that the right footing upon which to put the question of the beneficial action (or the reverse) of the Contagious Diseases Acts in a sanitary point of view is to inquire how much less disease of the peculiar kind against which the Acts are professedly directed there is now in the whole home army and navy than there was before these measures were enacted. It little matters what the fluctuating figures may be at one station now and at another next year, amongst a thousand men here or five hundred there, for a few months at one place and a few months at another. The question is, "Have these Acts—about the efficacy of which there have been so many boasts, about the pecuniary cost of which there can be no doubt, and concerning the outrageous indecency of which there cannot be two opinions—have they stamped out venereal disease in the army and navy? or, if they have not yet done that, are they on their way to it?—have they greatly diminished the number of admissions to hospital for these causes, and given us, as regards these diseases, healthier soldiers and sailors? I have now before me the Army and Navy Medical Reports for a number of years, the last—those for 1872—having just been issued. The tale these Reports tell—not in the letterpress, but in the figures—is a melancholy one for the supporters of the Acts. Here are the facts.

The total number of admissions per 1,000 men in the home navy in 1866, the year before any of the existing Acts for syphilis and gonorrhœa, was 89.5. In 1872 it was 126.7.

The number of men per 1,000 constantly sick of these diseases in the home navy in 1866 was 8.6. In 1872 it was 9.7.

The total number of men invalided on account of these diseases in the home navy in 1866 was 22 (out of a force of 21,200). In 1872 it was 51 (out of a force of 23,000).

All the great naval stations are under the Acts, and have been from an early period. And this is the result!

It is time that these facts were pointed out directly to the Government, and that the question was asked, "Why, in the face of such incontrovertible results, is the revolting system persisted in? Why, too, in the face of these unanswerable figures, are the compilers of the letterpress of the Report allowed to mislead Parliament and the public by reiterating the truthless declaration that the Acts are successful?"

In the army but half of the stations, at which 500 men and upwards are kept, are under the Acts, and this accounts probably for the fact that the evil results of the system are not

so broadly marked in the whole home army as in the whole home navy. Nevertheless, the utter inability of the system to stamp out disease is manifest from the fact that, whereas the total admissions for syphilis and gonorrhœa per 1,000 men in the whole home army in 1866 was 200.35, the number still stood in 1872 as high as 191.95. *Without the Acts* the number had fallen, between 1861 and 1866, from 262.09 to 200.35; *with the Acts* the rate of diminution had been materially checked, while the number of admissions for secondary syphilis, the worst of all the diseases, had increased, and was more in 1872 than in 1866, standing at 23.39 per 1,000 men in 1866, and at 24.26 per 1,000 men in 1872.

The number of men invalided also had largely increased. In 1866 it was 43 (out of a force of 59,758), in 1872 it was 96 (out of a force of 85,722), that is to say, it had increased from 7 to 11 per 10,000 men.

If the services be put together and the total admissions in 1866 and in 1872 be compared, it will be seen that the number in 1872, after six years' experience of the Acts, surpassed the number in 1866. This answers the question, "Have we healthier soldiers and sailors?" The two forces together in 1866 amounted to 80,958 men, and the admissions to 13,868, giving 171 per 1,000. The two forces together in 1872 amounted to 108,722 men, and the admissions to 19,373, giving 178 per 1,000.

It is unnecessary to add anything to these figures, the accuracy of which is unquestionable. They show unmistakably the failure of the Acts, and the extent to which the ruling powers of this country have been deluded. That the country will insist ere long on the total abandonment of the sham few reasonable men can entertain a doubt.

I am, Sir, yours faithfully,

CHARLES BELL TAYLOR, M.D., F.R.C.S.E.,
Surgeon to the Nottingham and Midland Eye Infirmary.

[We object to any argument founded upon the condition—as regards venereal disease—of the entire army and navy. The Contagious Diseases Acts are applied only to a few districts, not to the entire force, and there may, very probably, be causes for an increase of venereal disease in the part of the force which is not under control, which increase overwhelms the advantage gained within the controlled districts. The only fair deduction is derivable from a comparison of the prevalence of disease in the controlled and the uncontrolled stations.—ED. M. P. & C.]

MEDICAL AFFAIRS IN PARLIAMENT.

PUBLIC HEALTH (ENGLAND) BILL.

ON Thursday last, in accordance with previous notice, Mr. SCLATER-BOOTH moved for leave to introduce a bill for consolidating and amending the acts relating to public health in England, and in doing so he asked the house to favourably receive the measure, which both houses of parliament had frequently expressed a desire to see accomplished. The report of the sanitary commissioners of 1869 contained a very interesting account of the subject, going back to the reigns of Henry VI. and Henry VII., but for practical purposes the consolidation would be confined to legislation since 1848. The Public Health Act of that year was passed under pressure of considerable alarm arising from the approach of cholera. Both previously and subsequently to that date innumerable local acts had been passed, but since that time public attention had been more and more directed to this subject, and efforts had been made yearly to improve and facilitate local administration in the country. Many of them had been of a permissive character, and others had contained clauses partly permissive and partly compulsory, but cast upon different models, and they had approached the subject from different points of view, and contained provisions which touched, and in some cases conflicted with each other. The object of this bill would be to amend and reconcile many of them. Since the Provisional Orders Bill had been in operation a number of bills had been passed which contained provisions of law most objectionable to the whole community, and the sanitary

commissioners stated that the number of statutes that had been passed and the way in which they had been framed, had rendered the state of the sanitary law unusually complex, arising from the progressive and experimental character of modern legislation without any attempt at reconstruction or classification. The law was frequently unknown, and when studied was difficult to be understood. It was found impossible in passing the act of 1872 to comprise within it any consolidation of the law, but after two years' experience of its working an amended act was passed last year of a more uniform character. In fact, it would have been impossible to have worked the act of 1872 if a digest had not been prepared by the officials of the department. The time had now arrived for making a clean sweep of these acts, and 29 acts passed since 1846 would be more or less dealt with by this bill, with the exception of five or six clauses contained in them. And the few remaining provisions would be dealt with in future years. It was proposed to consolidate in this bill the Public Health Acts of 1848, 1859, and 1872; the Sanitary Acts of 1866, 1868, and 1870; the Nuisance Removal Acts; the Local Government Acts from 1858; the Sewage Utilisation Acts; the Towns Improvement Acts, and many others; and therefore he asked the house to allow the consolidated clauses to pass without much discussion and without opposition, and take them on the responsibility of his department, and with regard to clauses where the construction was doubtful, and the law was in apparent conflict, he would make known to the house the grounds upon which the proposed construction was placed upon them. The bill would make better provision as to the construction of sewers, and the local authorities would be empowered to obtain provisional orders under the Gas and Water Facilities Act; but it would not involve any question of competition with private companies, nor interfere with existing compulsory action. Powers would also be given for providing mortuaries in certain cases, and the meaning of overcrowded houses would be defined, which might be the case of one family only. Power would be given to the Local Government Board to group districts for the appointment of medical officers of a less clumsy and difficult nature than at present existed. Some provisions would also be introduced dealing with nuisances arising from smoke and offensive smells, to enable the present law to be more effectually put into operation, and the local authorities would be empowered to take such proceedings as were allowed under the present law whether the nuisance arose within or without their respective districts; and a person who contributed to a nuisance would not be allowed to escape the penalty, upon proceedings being taken against him, by pleading that he was only one of many parties who were guilty of the nuisance. The bill would in no way interfere with the provisions of the law that had been passed in the interest of trades and manufactures, but there would be an amendment so as to make the law reach those smoke nuisances that were exempt from the operation of the present law. Leave was given to introduce the measure.

PLEURO-PNEUMONIA.

At the same sitting, in reply to Mr. Barclay, Sir M. H. BEACH said that with reference to the question whether the Irish Government intended to make compulsory, as in England and Scotland, the slaughtering of animals afflicted with pleuro-pneumonia, he had pointed out to the House last session the difficulties which stood in the way of the introduction of such a scheme into Ireland as prevailed in England and Scotland. Since then the Irish Government had reconsidered the question, and an inquiry had been made by the Irish Veterinary Department, from which it appeared that there was no foundation for the statement of the spread of pleuro-pneumonia in that country.

PHARMACEUTICAL SOCIETY IN IRELAND.

In reply to Mr. Errington, Sir M. H. BEACH said he hoped to be able to introduce a bill this session for the establishment of a Pharmaceutical Society in Ireland.

ADULTERATION OF FOOD AND DRUGS.

On Friday, Mr. SCLATER-BOOTH obtained leave to bring in a bill to repeal the Adulteration of Food Acts and to make better provisions for the sale of food and drugs in a pure state.

CORONERS' (IRELAND) BILL.

In view of Mr. Vance's notice to introduce his Coroners' Bill for Ireland, it will interest our readers to be reminded of its nature.

An attempt was made during the session of 1872 to amend the law relating to the payment of coroners; it merely permitted grand juries to pay coroners a fixed annual salary, taking the *average* of their actual receipts for fees and mileage for five years as the amount to which they were entitled; but although the same Bill proposed to grant superannuation to secretaries of grand juries, county surveyors, and their assistants, it did not do so to the coroner. It is to be hoped, if a similar Bill is introduced next session, this injustice will be obviated, and that an office so ancient and useful will receive that consideration to which it is entitled.

During the last session of Parliament a Bill to amend the laws relating to the appointment, duties and payment of county coroners, and expenses of inquests in Ireland, was introduced by Mr. Vance and Sir John Gray. Its leading features were to empower coroners to appoint deputies, to abolish the property qualification—confining the election of future coroners to persons registered under the Medical Act of 1858, barristers-at-law, attorneys or solicitors, and justices of the peace of five years' standing—payment of coroners by salaries instead of fees, curtailing the polling at elections to one day, granting superannuation to coroners, power to discharge juries who disagree and swear a fresh one, power to take bail in cases of manslaughter, &c., &c. The Bill was read a second time, thereby affirming the general principle of the measure; but on the assurance of Sir M. H. Beach, the Chief Secretary for Ireland, that Government would prepare a Bill during the recess and submit it to Parliament next session, Mr. Vance consented to withdraw his Bill.

It is to be hoped a liberal measure may be introduced—one that will elevate this ancient office, and do away with the unseemly collisions between the constabulary and the coroners that have prevailed for the last year or two; for if the office is to be continued it should be maintained in its integrity, and supported by the authorities rather than depreciated—in a word, it would be far better to abolish the office than degrade it; but we hope to see it maintained, its character elevated, its usefulness extended, and its emoluments increased.

THE NEW ORDER OF MEMBERS OF THE DUBLIN COLLEGE OF PHYSICIANS.

In referring last week to the allegation of the "dissentients" that it was contemplated by the College to mulct the Licentiates in heavy fees in consideration of their advancement to the new rank, we stated that the "Dissentients had not produced a tittle of evidence of the existence of any such intention, and that, so far as we knew, no such proceeding was thought of. In order to meet the innuendo thus put forward, the Fellows, at their last meeting on the 12th, adopted unanimously the following resolution:—

"Resolved—That if the Charter be granted, giving the College the power of instituting an Order of Members, it is the opinion of the College that any Licentiate admitted before the granting of the Charter, who may desire it, may be transferred to the Order of Members without additional expense."

This is an explicit reply to the allegation of the "Dissentients," and a satisfactory guarantee to the Licentiates. As regards the *raison d'être* of the new diploma of Membership, the College has only to show that its Licentiates are really suffering under a substantial grievance, and the proposal to create the Membership can no longer be reasonably objected to. We observe in the columns of a medical contemporary and in a Dublin paper a vehement reclamation on the part of two Licentiates, resident in England, who state that they have been disqualified from office by

the want of a "Membership." If this be so in many instances the College has great justification for its wish to create such a degree.

The Surgical Society of Ireland will meet on Friday next, when communications will be made by Mr. Robert McDonnell, "On Cases, with Observations on the Relations of the Histology and Clinical Surgery of Tumours"; by Dr. Henry Kennedy "On the Strength of Muscle"; and by Mr. B. F. McDowell, "On Cases of Strangulated Hernia."

Gleanings.

Congenital Absence of the Bladder—Incontinence of Urine—Catheterisation—Death from Peritonitis.

At a recent meeting of the Société de Chirurgie, M. Gyon read for M. Fleury the following observation:—

A young girl who had menstruated since about a year previously, entered the hospital at Clermont for incontinence of urine of some months' duration. The vulva and the upper portion of the thighs were the seat of a painful erythema. A sound introduced into the canal of the urethra did not penetrate more than about an inch and a quarter. The vaginal touch showed relaxation of the vulvar ring, but furnished no further information.

Her general condition was good. Examination with the speculum was postponed until the following day. At that time the patient complained of pain in the belly; the skin was hot, the pulse frequent. The catheterisation had been carefully made, and these symptoms could not be accounted for. They increased in severity, and the patient succumbed a few days later.

The autopsy revealed an effusion of pus into the abdominal cavity, covering the folds of the intestines. The bladder was entirely absent, the ureters terminating on the sides of the urethral cul-de-sac. The left kidney contained creamy matter of a whitish-yellow colour; the right kidney was healthy. It was difficult to explain how, with such a vice of constitution the incontinence dated back only one year; later, however, M. Fleury learned from the patient's mother that this infirmity was congenital, but that it had become insupportable only within the last year. It is possible that within this time the urine had acquired an acidity which brought on the erythema.—*Bull. Gén. de Therap.*, Nov. 15, 1874.

Surgical Treatment of Oozana without producing Deformity of the Face.

DR. ROUGE, of Lausanne, has devised and executed the following operation. The patient being placed under the influence of an anæsthetic, the head inclined to the right, the upper lip is raised as high as possible. The gingivo-labial ridge of the first molar is then, on the right, incised to the left. All the tissues being divided, the anterior nasal spine is reached, and then the septum is detached from its base.

It is now possible to introduce the finger into the patient's nose and to explore the nasal fosse.

If necessary, a still larger way may be opened by dividing the cartilages of the *alæ nasi* at their maxillary insertions.

In nine cases operated upon by this process, it was possible to extract sequestra, to scrape the bone, and to cauterize fungosities. Cure followed in every case save one. Hæmorrhage somewhat abundant in a single case, was never sufficient to cause anxiety or to give occasion for the use of ligatures or hæmostatics.—*La Trib. Méd.*, July 19, 1874.

Infection by Syphilitic Semen.

DR. ISAAC SMITH jun. (*New York Medical Journal*), reports the following case, which he believes disproves the assertion of Professor Bumstead that it has never been proved that a female may, without becoming pregnant, contract syphilis through the semen of a syphilitic male, he having at the time no syphilitic lesion. A gentleman who had had chancre, secondary eruption, bubo, and engorgement and suppuration of the cervical glands, married after he had apparently been

in good health for about twelve months. Soon after, his wife had prolapsus uteri, and a chancre was discovered upon the os. This was treated, and healed kindly. Six weeks later she had a specific fever, and as that subsided, a secondary eruption appeared, which soon yielded to treatment. Six months afterwards, the man had urethral chancre, while his wife was suffering at the same time from engorgement of the os uteri, with uterine leucorrhœa. They were relieved of these troubles, and since then they have had perfect health. The woman has never been pregnant, and has never run past her time. The family is of the highest respectability.

Medical News.

Royal College of Surgeons of England.—The following member passed the required examinations and were admitted licentiates in midwifery at a meeting of the Board of examiners on the 4th inst., viz:—Messrs. William Hardman, Blackpool, diploma of membership dated July, 1874; George Herbert Lilley, Ware, Herts, May, 1874; George Albert Hamerton, Lambeth, July, 1874; and Charles Morgan Jones, Aberdare, South Wales, July, 1874.

Requests to Medical Charities.—By the will of Mr. G. Mullins, late of Kennington, Charing Cross Hospital receives a legacy of £1000; the British Home for Incurables £1000, and the London Truss Society £500. By the will of Mrs. Mary Ann Chantrey, late of Lower Brook Street, London, bequests of £300 each go to the Westminster Hospital, St. George's Hospital, Royal Free Hospital, and the Cancer Hospital, besides £200 to the Brompton Consumption Hospital. The Weston-super-Mare Hospital and Dispensary has received £450 under the will of Mr. Walter Tucker. Mr. Morton, of Wolverley, has bequeathed £100 to the Kidderminster Infirmary. The Royal National Hospital for Consumption, Ventnor, has received £100 from Mr. Reginald Bray. The Provident Dispensary and four other charities of Leicester have received £100 each under the will of Mr. William Hunt.

Lectures at the Royal College of Surgeons of England.—Professor Wilson, F.R.S., commenced his course of six lectures on Dermatology in the theatre of the Royal College of Surgeons on Monday last. The following is the syllabus of Mr. Wilson's lectures. General classification of diseases of the skin under three heads—inflammation, nutrition, and innervation. Preceding courses devoted to diseases of inflammation and part of those of nutrition. Diseases of nutrition are: dystrophic, atrophic, and hypertrophic. Dystrophic affections include: lepra, struma, lupus, lymphoma, xanthoma, and epithelioma. Atrophic affections: dermatoxer-asia, ichthyosis, saurosis, striæ atrophicæ, morphœa, and scleriosis. Dermatoxerasia, its relations with ichthyosis and saurosis; therapeutic considerations. Striæ atrophicæ, morphœa, and scleriosis; their pathology and therapeutic treatment. Hypertrophic affections: verrucæ, horns, and concretions, corns, angioma or vascular nævus, areolo-fibroma, areolo-fibrous tumours, and fibrous tumours. Verrucæ, their pathology; pathology of horns and concretions; therapeutical treatment of verrucæ; pathology of corns and their treatment; pathology and treatment of angioma. Pathology of areolo-fibroma; the Bosjeman; remarkable cases of dermatolysis; hypertrophic nose; spargosis; boucœmia; elephantiasis Arabum, therapeutic management. Areolo-fibrous tumours: acrochordon; spilus or tegumentary nævus; molluscum; fibrous tumour; cheloma; therapeutic considerations. Diseases of innervation: pruritus; prurigo; neuropathic excoriations; hæmorrhagic stigmata; illustrative cases: Louise Lateau's case. Hyperæsthesia; anæsthesia. Professor Parker, F.R.S., will commence his course of eighteen lectures on the Structure and Development of the Skull, in continuation of his course of last year, on the 15th instant.—The lectures of Professors Lee and Turner will be commenced some time in June next.

NOTICES TO CORRESPONDENTS.

NOTICE TO SUBSCRIBERS.—Subscriptions in advance for 1875, at the reduced tariff of 21s. per annum, post free, are now due, and will be thankfully received by the Publishers in London, Dublin, and Edinburgh.

MR. WHITTALL will find the subject referred to in another column. JENNER versus A CELESTIAL.—It has been stated that the Emperor of China's death was caused by the small-pox, whence it might be inferred that vaccination is not practised in the Celestial Empire. This however (*Galignani says*), is not the case; the virtues of the cow-pox were known to the Chinese many years before Jenner discovered it in our part of the world. We expect shortly to see the status of poor Jenner superseded by a gigantic pigtail.

PRESIDENTS.—We believe that the work to which you refer has been out of print for a long time.

PHYSICIAN TO THE EMPEROR.—The post of head physician at the Chinese Court would not appear to be very enviable. A despatch runs thus: "Emperor died on 12th January. Head Court physician decapitated."

MR. E. STEVENS.—The subject has more than once been brought under the notice of our readers; we cannot again refer to it.

THE SCIENCE OF HANGING.—In our last we quoted from a contemporary item of news that the Rev. Prof. Haughton was engaged on a work, "The Science of Hanging." Dr. Haughton informs us that there is not the slightest foundation for the statement of our contemporary. We are glad, therefore, to give Dr. Haughton's denial the same publicity as the erroneous statement referred to.

DR. GILMORE.—The suggestion is, we imagine, impracticable. How could the medical officer sit in judgment on deaths with which he might possibly be himself connected? (The Local Government Board set their faces against a dispensary officer being coroner under any circumstances. We will gladly cause your name to be enrolled on the list of members of the Irish Medical Association. The subscription will be 10s. 6d.

MEETINGS OF THE LONDON SOCIETIES.

WEDNESDAY, Feb. 17th.—Royal College of Surgeons, 4 p.m. Prof. W. K. Parker, "On the Structure and Development of the Skull."

FRIDAY, Feb. 19th.—Royal College of Surgeons, 4 p.m. Prof. W. K. Parker, "On the Structure and Development of the Skull."

ROYAL COLLEGE OF PHYSICIANS, 5 p.m. Dr. R. J. Lee, "On Puerperal Fever."

MEDICAL MICROSCOPICAL, 8 p.m. Dr. W. B. Woodman, "On a Natural Method of Mounting certain Microscopic Specimens."

MONDAY, Feb. 22nd.—Medical, 8 p.m. Ordinary.

TUESDAY, Feb. 23rd.—Royal Medico-Chirurgical, 8½ p.m. Ordinary. ROYAL INSTITUTION, 3 p.m. Mr. Alfred H. Garrod, "On Animal Locomotion."

WEDNESDAY, Feb. 24th.—Royal College of Physicians, 5 p.m. Dr. R. J. Lee, "On Puerperal Fever."

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

Cancer of the Uterus. By John M. Crombie, M.D. London: Mackay and Co.

Commentary on the British Pharmacopœia. By Walter G. Smith, M.D. London: Smith, Elder, and Co.

Heredity and Hybridism. By E. W. Cox. London: Longmans and Co.

VACANCY.

Naas Union. Medical Officer for the Clane Dispensary District. Salary, £125 per annum, with £15 extra as Sanitary Officer, and the usual vaccination and other fees. Applications to be addressed to the Hon. S.C., Clane Dispensary. (See Advt.)

APPOINTMENTS.

CARRY, C., L.R.C.P.Ed., M.R.C.S.E., Medical Officer for the Bromsgrove District of the Bromsgrove Union, and Medical Officer to the Workhouse.
 CARSON, S., L.R.C.S.Ed., Medical Officer of Health for the No. 2 Sub-district of the Alton-with-Garrigill Sanitary District.
 COOK, J., M.D., M.R.C.P.L., Physician, with charge of Out-patients, to the Great Northern Hospital.
 DAVEY, C. J., M.R.C.S.E., Assistant to the Extra Physicians at the Sick Children's Hospital, Edinburgh.
 EWEN, A. B., M.R.C.S.E., Medical Officer of Health for the Wisbech Port Sanitary District.
 FIELD, E., L.R.C.P.L., M.R.C.S.E., Resident Medical Officer to the Royal United Hospital, Bath.
 GLEESON, M. A., L.F.P. & S. Glas., Medical Officer for No. 5 District of the Fulham Union.
 GOEDIOCKE, F. W. E. W., L.F.P. & S. Glas., Medical Officer for the Milton District of the Gravesend and Milton Union.
 HACKETT, J. B., L.R.C.P.Ed., L.M., L.R.G.S.Ed., Medical Officer to the Workhouse and Fever Hospital of the Kilkenny Union, and Medical Officer, &c., for the Kilkenny No. 2 Dispensary District.
 HARDY, J. A., M.R.C.S., House Surgeon to St. George's Hospital.
 HARPER, G. S., M.R.C.S., House Physician to St. George's Hospital.
 HIGGINS, W. H., M.B., C.M., M.R.C.S.E., Assistant Medical Officer to the Derby County Lunatic Asylum.
 HOBLEY, S. H., L.R.C.P.L., L.R.C.P.Ed., Lecturer on Anatomy, &c., at the Hartley School of Science, Southampton.
 KENNEDY, D. M., M.D., Medical Officer for the No. 2 District of the Parish of Liverpool.
 LACY, C. DE LACY, L.R.C.P., Obstetric Assistant to St. George's Hospital.
 MACKAY, E. M.D., M.R.C.P.L., Acting Physician to the Birmingham and Midland Free Hospital for Sick Children.
 MARSHALL, H. F., M.B., M.R.C.S.E., an Extra Acting Physician to the Birmingham and Midland Free Hospital for Sick Children.
 MELLOR, Dr., Medical Officer for the Fylingdales District of the Whitty Union.
 NEWBY, T., M.D., M.R.C.S.E., Police Surgeon, Great Grimby.
 NICHOLS, Mr. D., Apothecary to the Steevens's Hospital, Dublin.
 SAMUEL, E., M.R.C.S., Medical Officer to the Llanelli Copper Works.
 SMYTH, J. M.D., Medical Officer, &c., for the Naas and Carragh Dispensary District of the Naas Union.
 SPARKS, E. I., M.B., M.R.C.P.L., a Physician to the Royal Infirmary for Children and Women, Waterloo Road, London.
 THORNTON, P., L.R.C.P.Ed., M.R.C.S.E., Medical Officer to the Greenwich Union Workhouse and Infirmary for one year.

Marriages.

ATTWATER-BUSH.—On the 3rd inst., at Burnopfield Church, Arthur Wm. Attwater, M.D., of Whickham, co. Durham to Louisa Isabella Gillett, second daughter of John Alderton Bush, of Bird Hill House, Whickham.
 HADDEN-HARLEY.—On the 3rd inst., at Christ Church, Leeson Park, Dublin, Dr. David Hadden, Wexford, to Charlotte Elizabeth, youngest daughter of the late Rev. John Harley, Rector of Taghmon.
 KEER-BRADY.—On the 3rd inst., at Tulloghobegly Parish Church, co. Donegal, Elias W. Keer, M.B., Kesh, to Fanny, daughter of Dr. George Fraser Brady, J.P., Falcarragh, co. Donegal.
 STOKER-TODD.—On the 5th inst., at St. George's Church, Dublin, Wm. Stoker, M.D., F.R.C.S.I., to Jennie M. Ross, eldest daughter of the late R. Moss Todd, of Dublin, Clerk of the Crown for co. Down.

Deaths.

CHATTAWAY.—On the 2nd Feb., A. G. Chattaway, M.R.C.S.E., of Kingsland, Herefordshire, aged 42.
 CRENNELL.—On the 6th Feb., at 47 Millman Street, Russell Square, London, Samuel Payne Crennell, M.D., formerly of H.M. Colonial Emigration Service, aged 57.
 CULLING.—On the 6th Feb., at Lydford House, near Somerton, Robert Culling, M.R.C.S., aged 52.
 JOYSON.—On the 4th Feb., John Joyson, M.D., of Brooksdon, Cranbrook, Kent, aged 85.
 KENNEDY.—On the 7th Feb., at Stratford Hall, Essex, Angus Kennedy, M.R.C.S.E., Surgeon to the South Essex Dispensary, aged 70.
 MORTON.—On the 5th Feb., at Waterloo Place, Dublin, Kate H., widow of Henry Morton, M.D.
 SMITH.—On the 10th Feb., Wm. Smith, F.R.C.S., of Moor Bank, Kersal, Manchester, in his 89th year.
 WHITE.—On the 4th Feb., F. B. White, M.R.C.P.L., of Tetbury, aged 32.

ROYAL COLLEGE of PHYSICIANS of LONDON.—
 Dr. R. J. LEE will Lecture "On Puerperal Fever" on Feb. 19, 24, and 26, at 5 o'clock.
 Members of the Profession will be admitted on presentation of their cards.
 By order of the President,
WILLIAM GURNER, Bedell.

ROYAL COLLEGE of SURGEONS in IRELAND.—
 Notice is hereby given that on Thursday, the 18th day of March next, at the hour of 2.30 o'clock p.m., the President, Vice-President, and Council will proceed, according to the provisions of the Supplemental Charter, to elect a PROFESSOR of CHEMISTRY, including Practical-Chemistry, in room of Mr. Reynolds, resigned.
 Candidates are requested to lodge their applications with the Registrar, at the College, on or before Thursday, the 11th March.
 By order, **JOHN BRENNEN,**
 Registrar.
 February 11th, 1875.

LECTURES on HOMOEOPATHY, instituted by the British Homoeopathic Society.—Course of Lectures on MATERIA MEDICA by Dr. RICHARD HUGHES.—The next Lecture will be delivered at the London Homoeopathic Hospital, Great Ormond Street, Russell Square, W.C., on Thursday next, February 18th, at 5 p.m. Subject: INTRODUCTORY ON THE HOMOEOPATHIC MATERIA MEDICA.
 Members of the Medical Profession will be admitted on presentation of their address cards. Medical Students can obtain admission on application to Dr. Bayes (Hon. Sec. to Lectures Committee), 58 Brook Street, W.

NAAS UNION.

CLANE AND TIMAHOE NORTH DISPENSARY DISTRICT.
MEDICAL OFFICER WANTED.—In consequence of the resignation of Dr. JOSEPH SMYTH, the Committee of Management will proceed to the election of a properly-qualified MEDICAL OFFICER for the above District on SATURDAY, the 27th of FEBRUARY, at 12 o'clock p.m., at a Salary of £125 per annum. The Medical Officer will also be entitled to £15 per annum as Sanitary Officer, and to Vaccination Fees. He will be required to reside in or near the town of Clane. Applications, with Diplomas and Testimonials, addressed to the undersigned, to be sent to the Dispensary, Clane, before 11 o'clock p.m. on the day of election.
 Personal attendance of candidates necessary.
 By order of the Committee,
MICHAEL DUNNE, Hon. Sec.
 Clane Dispensary, Feb. 10th, 1875.

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.
PATRON:—H.R.H. THE PRINCE OF WALES.
 This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.
 To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.
 The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.
 Pupils are admitted free by election, or by payment of £35 per annum. A higher rate is payable for separate accommodation.
 Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.
 Each donation of Five Guineas gives the donor a life-vote.
 Annual Subscribers are entitled to one vote for each half guinea paid.
 An Asylum for Lunatic Patients of the middle classes, under a well-organized administration, also forms part of the establishment.
 Full particulars as to the working of both Institutions, terms, &c. can be had at the office,
40 MOLESWORTH STREET, DUBLIN.
W. O'NEILL, Secretary.

DUBLIN INFIRMARY for DISEASES of the EYE and EAR, Ely Place.
Ophthalmic and Aural Surgeon:
ARCHIBALD HAMILTON JACOB, M.D. Dub., F.R.C.S., Ex-Ophthalmic and Aural Surgeon to the City of Dublin Hospital.
Consulting Physician:
EVORY KENNEDY, M.D. (Hon. Caus.) T.C.D. and Edin., Fellow and Ex-President King and Queen's College of Physicians.
Consulting Surgeon:
GEORGE H. PORTER, F.R.C.S.I.; M.Ch. T.C.D. (Hon. Caus.), Surgeon in Ordinary to Her Majesty the Queen in Ireland; Fellow and Ex-President, R.C.S.I.; Senior Surgeon to the Meath Hospital.
Obstetric Physician:
JOHN CRONYN, M.D., F.R.C.S., Professor of Midwifery, Roy. Col. Surgeons; Ex-Assistant Physician Rotunda Hospital.

Work, Income, and Expenditure for Twelve Months

Annual number of Dispensary patients
Number of visits paid by such patients	5,847
Number of patients within the Infirmary	124
Number of operations performed	163
Total gross expenditure per bed per annum	£27 15 0
Average expenditure per intern patient	1 10 6

The Infirmary is wholly dependent on private benefactions, and is in debt to the Medical Officer. SUBSCRIPTIONS ARE EARNESTLY SOLICITED

Established 1848.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S.,
 &c. (King's Coll.), and Author of VIA MEDICA.

Has always upon his books a large number of desirable Investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.
 Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

PRACTICES AND PARTNERSHIPS NOW OPEN for Negotiation (in addition to those advertised in Dr. Langley's List, which is sent post free on application).

Z 103. SPECIAL PRACTICE in scrofulous disease and cutaneous affections for TRANSFER. A well-established connection yielding between £1,500, and £2,000 a year after payment of working expenses. The books are in complete order, and a good introduction can be given. There are consulting rooms in London, and a professional residence in a good county town. The highest references can be given. Premium £1,500, of which £500 must be paid in cash.

Z 104. UNOCCUPIED PRACTICE for immediate SALE. Held by incumbent upwards of 20 years. Receipts £600 a year. Appointments £150. There is a convenient twelve-roomed house, with stabling, coach-house, greenhouse, large garden, and 4 acres of land. Rent £58. The vendor is retiring from the profession altogether, but will continue to reside in the district, giving to the successor such occasional assistance as he may require. A large part of the premium may be paid by instalments properly secured.

Z 105. FIRST-CLASS FAMILY PRACTICE in a good town, within 40 miles of London, with direct rail. Receipts £1,000 a year. Midwifery fees from £1 1s. to £10 10s. One horse and carriage sufficient for the work. The residence is one of the best in the town, with garden, conservatory, and every modern convenience. Being the property of the incumbent, it can be purchased or rented. The practice has been established upwards of 50 years, and the patients are a very good class.

Z 106. FIRST-CLASS PRACTICE in a pleasant provincial town, within 70 miles of London, with direct rail. The receipts average £800 a year. Patients good class. Very few midwifery cases. All appointments have been declined. The residence is specially fitted for professional purposes, contains twelve rooms, with detached surgery, stabling, &c., held on beneficial lease. Rent £70.

Z 102. YORKSHIRE. CAPITAL COUNTRY PRACTICE, yielding £500 a year. Introduction as long as desired. Ill-health the cause of retirement. The whole connection could be transferred to a suitable gentleman, by whom the connection could be largely increased. The greater part of the premium might be paid by instalments.

Z 101. PUBLIC APPOINTMENTS. The incumbent of several excellent appointments desires to introduce a successor in a good agricultural town about 40 miles from London. The salaries, &c., amount to £400 a year, and the premium for introduction would depend upon the success of the candidate; but a fee of £150 would be required to be paid on the resignation of the present incumbent.

The Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

ON NOXIOUS AND OFFENSIVE TRADES AND MANUFACTURES,

WITH ESPECIAL REFERENCE TO THE BEST PRACTICABLE MEANS OF ABATING THE SEVERAL NUISANCES THEREFROM. (a)

By H. LETHEBY, M.B., M.A., &c.,

Professor of Chemistry in the College of the London Hospital; late Medical Officer of Health and Public Analyst for the City of London; and President of the Society of Medical Officers of Health.

PART II. (continued.)

1. *Those which generate muriatic acid gas.* Until comparatively recently (since 1863, when the Alkali Act came into operation), the production of carbonate of soda, or rather salt-cake, which is the first step of the process of manufacture, was one of the most offensive and destructive operations in the kingdom. For a distance of miles, indeed, around the *alkali works*, vegetation was blasted, and residential existence was almost impossible. Action upon action at law therefore for ruinous damages was the chief entertainment of the parties concerned, and it was a dire struggle between the farm and the factory. The effect of all this was so seriously considered by the late Earl of Derby, that he brought it before the notice of Parliament and obtained the Act of 1863, which compelled the manufacturer of alkali to condense no less than 95 per cent. of all the muriatic acid derivable from the materials which were used; and last year the Act was amended so as to bring other manufactories, as copper works, where salt is the agent employed, as well as vitriol works, &c., under the Act. The amount of muriatic acid escaping from the alkali works is also restricted, not merely to 5 per cent. of the quantity made, but to one-fifth of a grain per cubic foot of the gas or air leaving

(a) From a paper read before the Society of Medical Officers of Health, January 16, 1875.

the works. There is hope, therefore, that still farther improvements will be effected in these operations.

The method of making salt-cake is first to treat common salt with sulphuric acid in pots (called saturating pots) at the head of a reverberatory furnace, and then to rake out the mixture upon the bed of the furnace, where it is subjected to a red heat for two or three hours. The muriatic acid, which is copiously evolved from the materials, is carried by pipes and flues to a high and capacious condensing tower, where it meets a stream of cold water flowing downwards over the coke with which the tower is packed. The draft of the tower is caused by the furnace shaft, into which the residuum of unabsorbed gas enters. In this way a liquid acid of 28 Twaddell (1,140 sp. gr.) is obtained, and this is used with oxide of manganese for making chlorine in the production of chloride of lime (bleach powder). The red hot salt-cake, when drawn from the furnace into iron barrows, is highly charged with muriatic acid, which it gives off in copious fumes, so that the workmen are obliged to take some precaution to prevent its effects. The fumes, however, do not extend to any great distance—not many yards from the furnace—and they might be checked altogether by Dr. Roscoe's contrivance of raking the hot furnace charge of salt-cake into a brick chamber underneath the furnace, and provided with an opening into the flue. All these arrangements are, however, under the immediate supervision of inspectors appointed by Government, and they are generally managed with great precautions.

Not so careful, as a rule, are the manufacturers who extract copper from spent pyrites by means of common salt. The iron pyrites used by the oil of vitriol maker in generating sulphurous acid contains from 2 to 4 per cent. of sulphur and a small proportion of copper. They are crushed into a coarse powder and mixed with common salt (3 cwt. to a ton of pyrites), and they are roasted in a reverberatory furnace for several hours, whereby muriatic acid gas and a little sulphurous acid escape; and as the manufacturers have not hitherto been under any legislative obligations as regards the proportion of acid evolved, they have generally let it go freely into the chimney

shaft. They will, however, be compelled to condense it by means of coke towers, as is done in alkali works.

Common bottle glass is now made from silica and common salt, which are fused together in huge melting pots, and thus immense quantities of muriatic acid gas are discharged into the air.

In like manner, the use of common salt as a means of *glazing the commoner kinds of pottery* (brown ware bottles, jugs, pans, pipes, &c.) is a cause of great offence at Lambeth and elsewhere, from the amount of muriatic acid discharged into the atmosphere.

Brick burning and cement burning are also sources of nuisance from the same cause. In the case of bricks, the salt comes from the cinders (household breeze) used in the burning, which become charged with salt in the dust bins of houses. In the case of cement burning, the salt is derived from the mud of the tidal rivers, from which, with chalk, the cement is made. In all these instances, when salt is heated with silica or clay, the alkali combines with the fixed acid and forms a fusible glass or glaze, while the volatile acid (muriatic) escapes. The remedy with the potter and cement manufacturer is to condense the fumes in a proper scrubber; and with the brick-maker the remedy is to use coke breeze, or household breeze that has been well weathered and washed by the rain.

2. *Nuisances occasioned by the escape of sulphurous acid.* This is most marked in the manufacture of oil of vitriol, which is always produced from the vapours of burning sulphur. The sulphur employed is either crude native sulphur or pyrites (which contains from 35 to 50 per cent. sulphur), and the spent oxide from gas works (which is a mixture of from 40 to 60 per cent. sulphur with hydrated oxide of iron and sawdust). The furnaces for burning these several forms of sulphur are very different in their construction, but when properly managed the combustion of the sulphur should be complete, or nearly so, and all the fumes should be carried, without escape, into the leaden chambers. These chambers are of great capacity, as from 30,000 to 100,000 cubic feet, and they not only receive the fumes of the burning sulphur (sulphurous acid), but they likewise receive nitrous fumes from a pot or small stove containing nitre at the back of the sulphur furnaces, as well as jets of steam, which are blown into the chambers from a boiler. The chemical reactions which take place in the chamber are not precisely understood, but the practical effect of them is that the sulphurous acid, or anhydride (So^2) with nitrous fumes (N_2O_3) and steam or water (H_2O) form sulphuric acid (H_2So_4), and nitric oxide (N^2O). The former is precipitated to the bottom of the chamber, where it is dissolved in the water present, and the latter (nitric oxide) escapes to take oxygen from the air of the chamber, and so again forms nitrous fumes for a similar reaction. The nitrous fumes, therefore, are merely the purveyors of oxygen from the air to the sulphurous acid, and would, in the presence of oxygen alone, act indefinitely; but as the oxygen of the air in the chamber is associated with nearly four times its volume of nitrogen, it follows that as the former is abstracted the latter accumulates, and must be replaced by fresh atmospheric air. Hence the necessity for a current of air through the chambers, and this current of air carries with it notable proportions of sulphurous acid and nitric oxide, which, escaping into the atmosphere by the chimney shaft, are the cause of injury to vegetation and annoyance to the neighbourhood. The extent of this escape of noxious gases may be determined in several ways:—First, the relation between the quantity of materials used and the amount of oil of vitriol produced. Theoretically, 100 parts of sulphur should produce 306.25 parts of monohydrated sulphuric acid (H_2So_4); but in practice it varies from 200 to 294 parts. The nitre also employed at the works ought not to exceed 2 parts by weight for every 100 parts of sulphur, but in reality it is rarely less than 4 parts, and it ranges from this to 12 parts or more. In those cases where spent oxide is used as a source of sul-

phurous acid, the quantity of nitre is rarely less than 7 per cent. Secondly, the amount of escape may be ascertained by examining the gases which pass from the chambers to the chimney shaft. There is always a means of doing this with considerable accuracy by abstracting the gases from the flues which connect the chambers with the general shaft. According to Dr. Roecoe, a cubic foot of these gases ought not to contain more than one grain of sulphur in any form; whereas, in badly managed works, the quantity may reach to sixteen grains per cubic foot. The air of the chimney shaft, also, should not contain more than a quarter of a grain of sulphur per cubic foot, and of this a little more than half is derived from the coke or coal burnt in the furnaces. The remedies for this waste are twofold:—1st. The exercise of care in the conduct of the works—regulating the sulphur furnaces so that no fumes escape therefrom, and a proper supply of air is admitted into the chambers. In well-managed works it is customary to have glass pressure-syphons communicating with the exterior of the various chambers, so as to watch and regulate the condition of them. The chambers also should be completely surrounded and enclosed with casing, having a gallery or passage way around, so that any and every escape may be at once detected. 2nd. The effluent gases should be passed through scrubbers charged with absorbent liquids. Oil of vitriol, for example, flowing through the scrubber in a small graduated stream, will absorb the oxides of nitrogen, as suggested by Gay Lussac; and water will take up any trace of sulphurous acid. Both of these liquids can be made to flow into the leaden chamber, and be thus utilised. At several oil of vitriol works which I have inspected, it is the practice to carry the gases, which may by accident escape from these absorbent agents, through a lime purifier, before they go to the tall chimney shaft; and in this way all chance of annoyance is prevented.

The sulphuric acid which collects at the bottom of the leaden chamber is continually drawn off at a specific gravity of 1,600. This is called "chamber acid," and as it is too weak for general purposes, it has to be concentrated by evaporation. This is done to a certain extent in leaden pans, where it reaches a gravity of about 1,720, making the "brown acid" of commerce; and the further concentration is effected in vessels of platinum or glass, where the acid obtains a gravity of from 1,845 to 1,854, which is the "oil of vitriol" of English commerce. All of these operations are offensive, from the escape of acid, unless they are well managed.

It is necessary, therefore, in the management of oil of vitriol works, to take care—

First, that the sulphur furnaces are burning properly, and are not permitting any escape of sulphurous acid.

Second, that the leaden chambers and flues therefrom are constantly sound and air-tight.

Third, that the gases in the flues from the leaden chamber do not contain above one grain of sulphur per cubic foot.

Fourth, that these gases are passed through a water scrubber and an oil of vitriol scrubber in succession, before they go to the chimney shaft; and

Fifth, that the evaporation and concentration of the chamber acid, as well as the brown acid, be conducted without the escape of offensive gases.

Another source of annoyance from the escape of sulphurous acid is where the *noble metals are refined* by boiling the alloys in oil of vitriol. This, however, is easily guarded against by conducting the operation in closed vessels and carrying the evolved gases through an alkaline solution, whereby valuable sulphites and hyposulphites may be obtained for commerce.

Lastly, there is often a considerable escape of this gas from the chambers where *bleaching operations* are carried on by means of burning sulphur, as, for example, in the bleaching of woollen goods, straw bonnets, hair, hops, spice, &c.; and in these cases the refuse gas should be carried through some absorbent liquid or solid (lime, for example) by means of a fan or draught to a chimney.

3. There are certain manufacturing operations which are attended with the escape of nitrous fumes, and are exceedingly irritating and offensive. As I have stated, these fumes may escape from badly managed vitriol works. They are also caused when oxalic acid is produced from saccharine matters by the action of nitric acid. Refiners also discharge large quantities of the acid into the air when they treat the alloys of the noble metals with nitric acid. The makers of tin and iron liquors, of nitro-benzole, and of picric acid, are likewise producers of these irritating fumes when they act upon the several materials with strong nitric acid. The remedy for the nuisance is the carrying on of such operations in closed vessels, and the conveyance of the nitrous fumes through water or an alkaline liquid (milk of lime), by which the red fumes are entirely absorbed or arrested.

In the manufacture of bleach powder (chloride of lime) there is occasionally an escape of chlorine, but it is nearly always accidental, unless the works are managed with great carelessness. The chlorine is generally made from the liquid muriatic acid, which flows from the condensing towers at the alkali works. The acid has a gravity of from 25 to 28 Twaddell (1,125 to 1,140) and it is run into a still upon peroxide of manganese, and stirred and heated so as to promote chemical action. The chlorine which is thus evolved is passed into chambers containing layers of finely slaked lime, slightly damp, to the depth of from 3 to 6 inches. The residual liquor in the still, which is a solution of chloride of manganese and free acid, of the strength of from 26 to 30 Twaddell, is, in many cases, not allowed to run to waste and be a cause of annoyance, but is treated with lime and air to recover the oxide of manganese. The first step of the process is to neutralise the free acid of the liquor by means of chalk (carbonate of lime), which does not decompose or act upon the chloride of manganese. When the effervescence is over, and the liquor has become clear by subsidence, the supernatant solution of chloride of manganese and chloride of calcium is drawn off into another vessel, called an "oxidator," where it is subjected to the action of a proper proportion of cream or milk of lime, which decomposes the chloride of manganese and forms a precipitate of oxide of manganese. Air is now blown into the mixture until the protoxide of manganese is converted into peroxide, and when this is complete it is allowed to settle, and the solution of chloride of calcium is either utilised or is run away to waste. Chlorine is also made from gaseous muriatic acid by the oxidising action of the air at a high temperature. In this case the muriatic acid gas from the salt-cake furnaces is carried with atmospheric air into chambers heated to a low red heat (about 1000° Fahr.), and here, and in another chamber called an "oxidator," the hydrogen of the muriatic acid is oxidised and the chlorine set free. The mixed gases and vapours of chlorine, muriatic acid, and steam, are passed through condensers to cool them, and the moist chlorine is finally dried in a sulphuric acid scrubber, and then conveyed to the lime chambers. This method of generating chlorine requires care and attention, as the high temperature of the decomposing apparatus is very likely to lead to fissures and cracks in the apparatus, which will permit an escape of irritating gases.

The last of the acid nuisances to which I shall refer is that caused by the manufacture of superphosphate of lime. In the early days of this branch of industry, it was the practice to make superphosphate of lime by mixing chamber acid, a little diluted with water, with ground coprolites, bones, and animal refuse of all kinds, by means of a shovel and an open trough. The fumes of acid gases and vapours which were thus freely evolved into the air were extremely offensive to the neighbourhood. At present the mixture is effected in a closed vessel, in which a stirrer revolves horizontally. The best form of mixer is about ten feet long and 4 feet in diameter, with a stirrer, which, with its arms, revolves horizontally. The materials which are used in the manufacture are ground coprolites, crushed bones, spent animal charcoal from sugar refineries, and animal refuse of all kinds. These are put into the mixer in proper proportions, and treated with water and sulphuric acid. The mixer has

an upper opening for the admission of the materials, and a lower one for the exit of them. Both of these openings are secured with covered air-tight valves; and during mixing, which lasts from five to ten minutes, the materials evolve vapours charged with organic fumes and the acrid and exceedingly irritating tetra-fluoride of silicon, which is produced by the action of sulphuric acid upon the fluorides and silicates contained in the coprolites. These gases and vapours are conveyed from the mixer by a special shaft or flue, which carries them first to a chamber, in which they meet a copious spray of water, and then through a coke scrubber or condenser, furnished with a fine stream of water; and lastly, in some cases, through a lime purifier before they reach the furnace shaft. When the materials are thoroughly incorporated in the mixer, they are discharged through the lower opening into the chamber or den, in which, in the course of twenty-four hours, they consolidate. This chamber should also be air-tight, and ventilated into the same shaft or flue which carries the gases from the mixer to the condenser. If these operations are properly managed, they may be conducted without other offence to the neighbourhood than the faint acid smell which is inseparable from the exposure of the consolidated superphosphate; but if they are not well designed and managed, they are the cause of insufferable nuisance. The object of having a fine spray of water, as the first absorbent of the acid gases, is that the tetra-fluoride of silicon is immediately decomposed when it comes into contact with water, forming the hydrate of silica, which is deposited in a pulpy form, and an acid called hydro-fluosilicic acid, which the water dissolves. Now, if this were to take place in a scrubber packed with coke and supplied with downward flowing water, this hydrate of silica would soon clog the pores and apertures of the scrubber, and throw it out of action. Hence the necessity for decomposing the tetra-fluoride of silicon in a chamber before it reaches the coke scrubber.

SUMMARY.

And now, in concluding this brief outline of the processes which are most likely to receive attention from medical officers of health, I may summarize the recommendations which I have ventured to submit as the best means of abating the nuisances referred to by saying:—

First, that all noxious and offensive operations should be carried on, as far as possible, in air-tight chambers, which can be ventilated by means of fans, or by the chimney draft.

Second, that all condensible and absorbable gases and vapours should be passed through condensers and absorbents best suited for their absorption—as water in spray, and scrubbers charged with water, oil of vitriol, or alkaline solutions.

Third, that when necessary, these scrubbers should be supplemented with special purifiers, as hydrated oxide of iron, hydrate of lime, &c.

Fourth, that organic vapours and sulphuretted hydrogen and empyreumatic matters should be conveyed to the furnace fire and destroyed. In carrying out this part of the process, it is necessary that all steam should be condensed from the vapours, by cooling them thoroughly before they reach the fire, as otherwise the fire is apt to be put out by them. The fire which is best suited for this purpose is that which is actually used in manufacturing operations, as special fires are very likely to be neglected; and the best place for the entrance of the noxious vapours is at the back of the ash-pit immediately under the fire-bars, as by this means a draft is secured (by closing the ash-pit), and the vapours are made to pass through the glowing coals of the fire.

Fifth, all offensive materials should be brought to the works, or carried away from them, in properly constructed carts or tanks, which can be closely covered; and all such material when stored at the works should be kept in close tanks or chambers, ventilated, when necessary, to the scrubbers or furnace fire.

Lastly, the whole of the operations should always be managed with care and attention to details—there being no neglect of the sound condition of every part of the plant or working apparatus.

With these precautions, which are by no means unreasonable or impracticable, the manufacturer of offensive products might generally so conduct his operations as not only to protect the public from annoyance, but also to secure his own interests by preventing unnecessary waste.

It will be observed that I have not dealt with the question of nuisances from the slaughtering of cattle, &c., as this has already received attention from the society, through the labours of our colleague, Dr. Dudfield, and that our recommendations on the subject have been accepted by the Metropolitan Board of Works.

In conclusion, I trust that I may soon be able to find time for a further treatment of the subject by describing the nuisances which arise from the second and third causes alluded to at the beginning of the paper.

ON CERTAIN RECENT THERAPEUTIC REMEDIES. (a)

By W. HANDSEL GRIFFITHS, Ph.D., L.R.C.P. & S.E.,

Corresponding Member of the Therapeutical Society of Paris; Honorary Member of the Ontario College of Pharmacy; Editor for the *Edinburgh Medical Journal* of the "Monthly Reports on the Progress of Therapeutics;" Librarian to the Royal College of Surgeons in Ireland.

MR. PRESIDENT,—In your address at the opening of the present session you dwelt in forcible terms on the liberality on the part of the founders of this society in admitting for consideration other than purely surgical matters.

In the exercise of my duties as editor for the *Edinburgh Medical Journal* of the "Monthly Reports on the Progress of Therapeutics," I am obliged to keep myself *au courant* with the advances of therapeutical science. I have therefore thought that a brief review of some of the more important remedial agents which have of late occupied attention would not be regarded as wholly unprofitable or altogether devoid of interest.

Thanks to the courtesy of many donors, I am enabled to exhibit a valuable collection of illustrative specimens, most, if not all, of which are now exhibited in Ireland for the first time.

I must state at the outset that, with one exception, I have but little practical experience of any of these drugs to which I am about to allude. I cannot therefore be considered as endorsing any opinion which I may have occasion to quote.

The first substance to which I would ask your attention is—

GOA POWDER.

Inasmuch as this is a secret remedy, I would not allude to it were it not that it has been the subject of a recent paper by Dr. Fayer, in the *Medical Times and Gazette* (Oct. 24, 1874). That authority speaks highly of it as a remedy for Indian ringworm.

The following is the mode of applying the powder: A few grains are dissolved in lemon-juice or vinegar, to about the consistence of cream; this is painted over the eruption and for some little distance beyond its margin on the sound skin. There is no pain at first, but in a few hours there is a dull heavy sensation, as though the skin had been bruised; the eruption becomes white, whilst the

surrounding skin is stained a dark brown. The sense of uneasiness soon passes away, the integument assumes its natural character and all traces of the disease disappear. Dr. Fayer concludes, "Whatever it may be, there can be no doubt of its efficacy in the treatment of the skin diseases I have alluded to, and I should think most probably it might be useful in others also. I venture, therefore, to commend it to the notice of dermatologists, and to hope that its efficacy may be further tested in the treatment of skin diseases."

Mr. George Gaskoin, surgeon to the British Hospital for Diseases of the Skin, to whom I am indebted for the specimen on the table, entertains by no means so high an opinion of this remedy. He says that on the whole his experience is such as not to lead him to praise the drug. He says that it gives an ugly brown stain, which is followed by an amount of inflammation which equals that from the coarsest remedies (a). The preparation which Mr. Gaskoin employs he obtains from Mr. Garrad, of Leamington; it bears the Government stamp of the Bombay Presidency, and is sold by Messrs. Kemp and Co., of Bombay and Poonah.

According to Mr. D. S. Kemp, (b) Orchella-weed (*Lichen orcella*), exported from the coast of Africa north of Mozambique to India, is the most probable source of *goa* powder.

CONDURANGO.

A brief allusion to this drug may not be uninteresting. Heralded as a cancer-cure, it has been tried and found wanting. The excitement to which its reputed wonderful powers gave rise caused it recently to command enormous prices, especially in New York. Although it has proved worthless in the treatment of cancer, testimony as to its remedial powers in other affections is very strong.

In a recent paper by Professor C. Andrews, (c) of Chicago, he attributes to it a marvellous power in promoting the growth of granulations in ulcers.

It will probably be of use in the treatment of syphilis, scrofula, and chronic blood-diseases.

Condurango most probably belongs to the *N. O. Asclepiadaceae*. I shall not further allude to it than to state that a good description of its botanical characters is given in the *Pharmaceutical Journal* for November 18, 1871, and by Mr. Alfred Bennett in the eighth volume of the *Practitioner*.

For the specimen which I have the pleasure of exhibiting I am indebted to the Director of the General Apothecaries' Company of London.

GUARANA.

I have to thank the same gentleman for this specimen of guarana, a drug in which much interest has lately been centered.

Mr. Joseph Hallawell, in the *Chemist and Druggist*, March, 1873, gives a very good description of the mode of preparing the drug. *Guarana sorbilis*, the plant whence guarana is obtained, grows in a wild state to thirty or forty feet. It produces fruit in three years after planting, and the plant lives for forty years. The Indians remove the ripe seeds from the capsules and dry them in the sun; they are then slightly roasted and powdered; the powder is moistened, and exposed to night-dew, in order to form a paste, which is rolled into cylinders and dried. It has a bitter styptic taste, and is softened and partially dissolved by water. In Brazil it is used as a remedy for diarrhoea and dysentery, and as a tonic and stomachic. It is, however, for its efficacy in the relief of sick-headache that it is chiefly valued. The dose is half a drachm to a drachm. Dr. W. Macdowal (d) states that in experiments on himself and others he found that it will completely prevent

(d) Read before the Surgical Society of Ireland, February 5. The discussion will be found at page 163.

the feeling of fulness of the head, lassitude and sleepiness following a full meal.

Dr. Edward A. Rawson, of Carlow, has tried the effects of this drug on himself and others. That gentleman has the misfortune to suffer occasionally from lumbago, but he has found in guarana an unfailing remedy. He writes: (a) "I have come to the conclusion that whenever the fibrous envelopes of nerves, the aponeurotic sheath of muscles, the fasciæ or tendons are the parts affected, guarana gives, if not instantaneous, at least, very immediate relief, which will last from twelve to twenty-four hours; and I confidently expect that perseverance in the use of the drug, gradually increasing the dose up to 40 grains, will entirely remove any of the above-mentioned kinds of rheumatism. Of the good effects of guarana or nervous hæmicrania there is no doubt, and I trust it will prove in other hands as valuable against rheumatism as it has in mine."

RHAMNUS FRANGULA

Was first recommended as an aperient in 1843 by Mr. George Mennie, of Plymouth. It is the subject of a recent interesting paper by Mr. Joseph Ince, (b) to whom I am indebted for the specimen on the table. That gentleman characterises it as "a non-drastring, safe, pleasant, and efficient purgative," and some surgeons who have tried it state that it counteracts habitual constipation in a marvellous manner when all other remedies have lost their power. (c) The following formula is extensively used in Holland: Four drachms of the bark and a pint of water; boil down to half-a-pint. The dose of this for an adult is two or three-tablespoonful night and morning.

JABORANDI.

I have now to submit to the notice of the Society specimens of jaborandi, probably the first ever imported into Ireland, and for which I have to thank Professor Sydney Ringer and Messrs. Morson and Sons, the eminent pharmacists of London. The plant was but very recently brought from Pernambuco to Paris, by Dr. S. Coutinho. We are not yet in a position to state with any degree of certainty what is the botanical origin of jaborandi. Prof. Baillon believes it to be identical with *Pilocarpus pinnatifolius*, N. O. Rutaceæ, and Prof. Oliver also believes it to be a rutaceous plant. Mr. Martindale, (d) however, seems to think that it may be the produce of one of the *Piperaceæ*.

M. Rabuteau has investigated the chemistry of this plant, and finds that it contains an inert volatile principle, an inert substance tasteless and soluble in water, and a substance with a bitter taste which is soluble in alcohol, and on which the effects of the drug depend. He did not find any alkaloid or definite active principle.

The physiological action and therapeutic use of jaborandi have been the subject of investigation by MM. Gubler, Rabuteau, Robin, Ball, Hardy, and others in Paris, and by Prof. Sydney Ringer in this country. I believe I am correct in stating that these investigators are agreed in assigning to this drug the foremost position as a sudorific.

At a recent meeting of the Société de Thérapeutique, M. Albert Robin (e) communicated the results of his investigations as to the action of jaborandi. He found that under its influence the urea and urine are at first diminished in quantity, but that after some days the quantity of these and of uric acid and chlorides are increased. It seems to act on the vaso-motors, diminishing tension by paralysing them, thus facilitating the passage of blood through the cutaneous capillaries. It is important to notice that in cases in which it was given in minutely divided doses there was no sweating or salivation, but copious diuresis. In the *Practitioner* for December, Prof.

Sydney Ringer details the results of his trial of jaborandi. In three out of four cases he found it to cause copious perspiration. In one case the skin remained quite dry. It acts as a sialogogue, sometimes causing a very great flow of salivary secretion, but its action in this respect is less uniform than its diaphoretic action. In one case only did it increase the bronchial secretion. It accelerates the action of the heart, and renders the arterial impulse more visible. In each observation the temperature fell considerably. In all cases vomiting was excited, but with scarcely any nausea. It produced drowsiness, which supervened when the flush disappeared from the face and the skin became pale. The perspiration continued profuse long after the flush had left the face.

I was very anxious to test the effect of this drug on my own person. I therefore took forty grains infused in boiling water. I will content myself at present by stating that in less than fifteen minutes I was covered with a profuse perspiration, which lasted for over an hour and a half. As I purpose a careful study of the effects of this very interesting drug on my own person, I trust that at an early date I shall be enabled to submit the results to this Society.

BOLDO.

The Society will probably regard with interest this very perfect specimen of boldo—the new tonic—kindly presented to me by Messrs. Savory and Moore, chemists to the Queen. This drug, which has recently attracted much attention, was first described in 1782, by Molina, as *Peumus boldus*, N. O. *Monimiaceæ*. The leaves are the part used, on account of the aromatic oil which they contain. The drug has not yet been used in this country, but in France it has been experimented with by Dujardin, Beaumetz, and Claude Verne. It has been found to act as a stimulant to digestion, and it exerts a powerful influence on the liver. The leaves when fresh are green, but change on drying to a reddish-brown; they are opposite, entire, and oval; they have an aromatic taste and odour, are coriaceous in texture, and are covered on their surface with small glands. The most abundant product yielded by the plant is the essential oil, and an alkaloid termed boldine has also been discovered by M. Verne and M. Bourgoin. Beaumetz commences the administration of boldo with a dose of fifty centigrammes of an alcoholic tincture made by macerating 100 grammes of the bruised leaves in 500 grammes of 60° alcohol, and filtering. This dose may be increased to two grammes daily, but it should be remembered that large doses produce vomiting.

I have now to request the attention of the Society to this specimen of

EUCALYPTUS,

Which was presented to me by the Director of the General Apothecaries' Company of London. The plant is the *Eucalyptus globulus*, N. O. *Myrtaceæ*. Eucalyptol, obtained from it, is a liquid camphor (C₂₄H₂₀O₂), and possesses nearly all the active properties of the plant, which does not contain an alkaloid. A moderate dose of eucalyptol (10 to 20 drops) at first accelerates the pulse, produces general excitement, a feeling of buoyancy, increased appetite, strength, and sexual desire. Its effects are not followed by torpor, but it produces calmness and a soothing sleep. After the stimulating effects have passed away it diminishes arterial tension, and the temperature falls; the pulse becomes less frequent, and the senses are blunted; the functions of the brain are not affected; the size of the pupil is unaltered; the reflex functions of the cord are depressed. When fatal it kills by destroying the excitomotor functions of the cord, and the temperature falls rapidly.

The following are Gimbert's conclusions as to its therapeutic use: (a) It is antiseptic. It is a powerful general stimulant through its primary action on the nervous centres and sympathetic, whereby it quickens the capillary circulation. Through its influence on the nervous

(a) *Arch. Gen.*, Feb., 1873.

system it is antispasmodic. By diminishing the excitomotor activity of the cord, by lessening animal combustion, the frequency of the respiration, and of the circulation, it becomes febrifuge and sedative.

According to Siegen (a) eucalyptol exerts quite as powerful an antiseptic action as quinine, and it depresses the temperature of the body more than that substance. Siegen considers that eucalyptol in large doses is of great value in the treatment of febrile diseases of the respiratory organs, especially whooping-cough. It is but fair to state that Dr. E. Burdel (b) does not think so highly of this drug. He considers that as a febrifuge it is slow and inconstant in its action; and in the treatment of ague he finds it in every respect inferior to quinine.

GELSEMINUM.

The last drug to which I shall allude this evening is gelseminum, or yellow jæmin. The specimen which I have the privilege of exhibiting was given me by the Director of the Apothecaries' Company of London.

The dose of the powdered root is 1 to 2 grains, and a tincture may be made by macerating two ounces of the root in a pint of rectified spirit; of this fifteen minims may be given every six hours.

In neuralgic pains of the face and jaws associated with carious teeth, but unconnected with local inflammatory changes, it proves most beneficial after the third or fourth dose.

The symptoms produced by an over-dose would be dimness of sight and great prostration. The following are the evidences of its physiological action: Loss of sight, double vision, headache, and paralysis. (c)

Dr. W. C. Hull, of Monroeton, Pennsylvania, communicates an interesting paper on gelseminum to the *Philadelphia Medical Reporter*. According to this author, gelseminum acts directly on the great sympathetic, diminishing the amount of nervous force transmitted through the vaso-motor system of nerves to the capillary vessels, impairing their tonicity and producing congestion. Gelseminum is not an arterial sedative as veratrum viride is. The latter drug is adapted to the treatment of congestive and inflammatory diseases, for, by directly restraining the heart's action, less blood is forced into the weakened and distended capillaries, and resolution is facilitated. On the other hand, gelseminum is contra-indicated in such conditions, as it indirectly restrains the heart's action by first producing general capillary congestion, a morbid state which generally aggravates existing local lesions. The following are Dr. Hull's conclusions regarding the use of gelseminum.

1. It is not adapted to the treatment of inflammatory and congestive diseases.
2. It inflicts positive injury in active congestion.
3. Its therapeutic scope does not extend much beyond certain simple forms of fever.
4. In order to obtain its specific action in fever, it must be rapidly introduced into the system, until its characteristic effects are produced on the organs of vision.
5. It can be given in full doses with entire safety in those cases to which it is adapted.

Dr. J. D. McGaughy, of Wallingford, Connecticut, writing to the *Philadelphia Medical Times*, March 7th, relative to the use of gelseminum in intermittent fever, says: "I feel pretty well assured that, if physicians will give gelseminum a fair trial in connection with quinine, in cases where quinine alone has failed to cure, they will meet with gratifying success, provided they push the gelseminum until its physiological effects are produced." Dr. William W. Murray, of Baltimore, expresses his conviction that "it is not only equal to quinine in breaking in upon the chain of morbid phenomena which characterise intermittent

fever, but that it is infinitely superior to that article in curing the disease." (a)

I had hoped to have been enabled to allude this evening to croton-chloral, monobromide of camphor, apomorphia, and other remedial agents of great interest, these very beautiful specimens of which have been presented to me by M. Clin, of Paris, M. Dufourcel, and Messrs. Smith and Son of Edinburgh. I was also anxious to exhibit this extremely valuable collection of alkaloids presented to me by the latter firm. I trust, however, that before the close of the session I shall be afforded an opportunity of submitting these substances to the attention of the Society.

In conclusion I beg to say that I purpose devoting my somewhat scanty leisure to a painstaking investigation as to the physiological action and therapeutic use of the drugs which I have this evening described, and I am not without hope that at some future meeting of the Society I shall be permitted to detail my results.

A METHOD OF CURING SOME OF THE CONTRACTIONS IN THE NEIGHBOURHOOD OF JOINTS THE RESULT OF BURNS AND SCALDS. (b)

By F. J. B. QUINLAN, M.B. Dub.,

Surgeon to St. Vincent's Hospital and Professor of Materia Medica in the Catholic University.

EVERY practical surgeon is familiar with the distressing deformities which are liable to be brought about by the contraction of the organised lymph forming the cicatrices which ensue after severe burns or scalds. When such an injury has destroyed the skin and subcutaneous areolar tissue, after the separation of the slough, a tedious form of granulation supervenes, converting the area of the injury into an ulcer, which gradually becomes covered with a pearl-coloured cicatrix. This cicatrix undergoes a slow but powerful process of contraction, and, although when it is situated in the extension aspect of a joint the power of that joint frequently counteracts it, still, when it is placed on the aspect of flexion of the knee or elbow, or when it extends from the sternum to the chin, the most disfiguring results are produced: the elbow is bent close to the side, the forearm is flexed against the arm; the knee bent to a right or acute angle; or the head bowed down upon the breast; the long disused muscles begin to atrophy, and finally the limb becomes a disfigurement and a burthen instead of a useful instrument. In some of the severer cases important vessels and nerves become involved in the cicatrix, rendering surgical interference difficult, if not impossible.

The great inconvenience consequent upon these deformities and the difficulty of dealing with them have tasked the ingenuity and perseverance of the surgeon, and have led to the invention of a long series of operations—plastic and otherwise—for their relief. It would be a long and (in this place) an unnecessary task to enumerate these operations. I believe that most of those here will agree with me in saying that the results are seldom encouraging. Sometimes the operation fails *ab initio* by the healing up of the incisions in nearly their old state. Sometimes temporary relief is given by the formation of a new cicatrix, which, however, in its turn takes up the contractive process, and leaves things as bad, if not worse, than before. Sometimes plastic operations are attended by serious results, on account of hæmorrhage, the implication of nerves or blood-vessels, or the supervention of erysipelatus

inflammations. I venture this evening to describe a case treated upon a plan which is, at all events, new to me, although I cannot, of course, say that it is so to others. It is simple and very safe; it is expeditious, and comparatively painless; it is not troublesome to the surgeon, and in the case in question yielded a satisfactory result, permanent to the extent of twelve months. I can at least do no harm by bringing it under the notice of so many practical surgeons, who will, if they are not already acquainted with it, give it a fair trial.

Theresa Masterson, *æt.* 9, a girl of very healthy appearance, residing in the county Kildare, was admitted into St. Vincent's Hospital on the 3rd October, 1873. Her right arm was bound to her side by a cicatrix, thin, but of great strength and rigidity, extending from the internal condyle of the humerus to the axilla, the utmost extent that she was able to separate the arm from the side being about two and a half inches. The motion of the elbow-joint was unimpaired. The mother informed us that when about four years old the child's clothes caught fire by her approaching too near the kitchen grate, and she was severely burnt on the right side of the chest and the inside of the right arm. A bystander, with much presence of mind, seized the child, and plunged the burning part of her body into a large tub of water which was fortunate at hand; and to this circumstance is to be attributed the fact that the burn was so severe in character while so limited in extent. The treatment appears to have been conducted in the ordinary manner, and with the ordinary results, leaving the child in the condition described. At six years her right arm was useless, and, although she grew up left-handed, still the inconvenience and disfigurement caused her mother to try whether anything could be done to relieve her.

I at first endeavoured to open the cicatrix upon the "ear-ring" principle. By this I mean that I pierced it beneath the axilla with a trocar and canula, and introduced a very smooth glass rod, about a quarter of an inch in diameter. This was every few days taken out, cleaned, and replaced, the hope being that the tunnel through which it passed would by degrees become lined with cicatrised cuticle in the same way as occurs when the lobes of the ears are pierced for the reception of ear-rings. This object being accomplished, a probe-pointed bistoury is introduced into the tunnel, and the cicatrix is divided outwards. Two islands of raw surface are of course formed, separated by the epithelium which had lined the tunnel, but which is now opened out. These raw surfaces are treated as ulcers, and gradually healed up.

This plan, theoretically speaking, looks well enough. It is well known that healthy action will take place pretty readily in healthy tissue around smooth, non-rusting, and non-absorbing foreign bodies. Musket-balls have become encysted. The use of gold ear-rings is almost universal among our female population, and in the south of Europe among both men and women. Nay, more, the aboriginal inhabitants of the Pacific Islands succeed in fixing in their noses and ears ornaments of pearl, ivory, or fish-bone, upon the same æsthetic principles that we use ear-rings. The introduction of ear-rings is an operation constantly performed by the jeweller, but scarcely ever by the surgeon. I have been informed that these punctures almost invariably heal up quickly around the foreign body, and upon this I relied in the "ear-ring operation." I overlooked, however, the important difference which exists between operating upon a healthy ear and upon a cicatrix. I tried it in quite a number of cases. I pierced the cicatrix with a trochar, gas cautery, hot wire, &c.; I tried glass, metal, and ivory; but the result, except in two cases, was the same—the tunnel would not heal. It would suppurate, ulcerate, but would not skin over. In two very healthy children, suffering respectively from a contracted neck and forearm I succeeded by long patience. The rest had to be given up.

When my little patient was admitted I thought I would try this process upon her, as she was from the country, and very healthy. With a trocar and canula pressed

against a cork I introduced the glass rod just as one bores for a common ear-ring. For a long time she did well, but unfortunately was attacked by erysipelas. The rod had to be removed. The tunnel healed up and became obliterated, and we were left *in statu quo* after two months of treatment. Thinking it perfectly useless, after the erysipelas, to recommence the process, I cast about for some other plan, and tried the following:

Entering the trocar about the same spot as before, I inserted a piece of india-rubber cord, quarter of an inch thick, and tied it in the usual way at the lower margin of the cicatrix. It cut its way rapidly through, and when its elasticity was exhausted was replaced by another piece. The cicatrix was divided in three days, the process being completed with an *écraseur*. There was, of course, no hæmorrhage, but already there was granulation at the axillary end of the cut, and the adhesive process, which would leave matters just as bad as before, was commencing. Taking a long, narrow piece of lint, spread with calimarnis ointment, I applied it to the cut surface of the inside of the arm, the axilla, and the side of the chest. I now passed an india-rubber ring over the forearm and arm, and placed it so as to press upon the shoulder above and the cut surface of the axilla below. The arm was finally lightly bound to the side.

Not to delay the Society with details, I may say that the process went on satisfactorily. The granulations, occasionally stimulated with lunar caustic, continued healthy. At last both the inside of the arm and the surface of the chest became skinned over, the only sore spot remaining being that where the india-rubber ring pressed upon the axilla. A lighter ring was now applied with dry lint to the arm and chest. At last the axilla healed up also, and the arm was comparatively free six weeks after the commencement of the second process. Passive motion of the arm upon the shoulder was now employed, and was actively seconded by the companions of the child, who used to amuse themselves by trying how high they could raise the arm. Finally, when the child was discharged, about the middle of last March, she could touch the occipital protuberance with her right fingers while very slightly inclining the head. She could also touch her right shoulder and the small of the back. When I heard of her in autumn she was still doing well. She continued left-handed.

It will of course be evident that in contractions where the chin is bent down upon the sternum this operation would be out of the question, on account of the intolerable pressure which would be brought upon the respiratory and circulatory passages. When we have a fulcrum of support on the shoulder, patella, or olecranon, and when the impeding bone is thin, I think the operation is worthy of trial. It is of course impossible to generalise from a single case. Even in this case the result may not stand the test of time, but, as has happened before in instances just as promising, the deformity may slowly recur. The method is, however, as I have said, expeditious, painless, simple, and free from risk, and worthy of further trial. For the great deformities of the hands and feet which we so often meet with, it would, I think, be hardly applicable, its use being more or less restricted to the cases above mentioned.

Transactions of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.
TUESDAY, FEBRUARY 9TH, 1875.

C. J. B. WILLIAMS, M.D., F.R.S., President, in the Chair.

HYPOSPADIAS AND EPISPADIAS.

MR. JOHN WOOD exhibited some cases of hypospadias and epispadias, on which he had operated. Two of the cases of

hypospadias were boys, who had been unable to pass urine in the erect position, but were obliged to crouch down. The stream passed backwards. Having previously, in other cases, tried various plans with unsatisfactory results, he adopted in these cases a plan which he had found successful in two other patients some time ago. It consisted in making a hole in the prepuce, through which the glans was made to protrude—the operation being somewhat the reverse of that of Nélaton for epispadias. At first, he did not realise the difficulty of properly adjusting the parts; but he succeeded by making a broad flap and turning the skin inwards to the urethra. The prepuce was utilised for the formation of a channel for the urine. In one of the cases there was a *cul-de-sac* apparently representing the fossa navicularis, with the urethral opening behind it. This he slit up so as to form a continuous channel. In the case of epispadias there was want of retention of urine; but this defect had been quite overcome by first operating by Nélaton's method, and then performing two subsequent operations for completing the channel.

ON THE TREATMENT OF FISTULOUS OPENINGS BY DILATATION.

By WM. MURRAY, M.D., of Newcastle-on-Tyne.

The author had been induced to try the effect of dilating sinuses by tangle-tents, because of the contraction which sometimes follows their use, on the principle that the lymph which is effused by the inflammation of rapidly dilated tissues will sometimes close a sinus by its subsequent contraction. The treatment was tried in a case of fæcal fistula at the umbilicus; and, after two or three dilatations, a barrier of lymph was effused which, by its contraction, closed the opening. In a case of fistula in the cheek, the same success was rapidly obtained. In a curious case of fistula of the urethra, the canal was closed after one or two dilatations, other surgical treatment having completely failed. In ordinary sinuses connected with strumous glands, good results were obtained by dilating, so as to let out curdy matters, and by setting up adhesive inflammation. The author asked surgeons to test the treatment in other cases, and suggested the use of tents for opening up sinuses connected with diseased bones and foreign bodies. By so doing, the parts might be explored, and the offending substance might be removed without cutting.

Mr. JOHN WOOD would not detract from the merit of originality in the paper; but the proposal to dilate a sinus leading to dead bone was carried out long ago by Nélaton, by means of a piece of gentian-root, in Garibaldi's case. The plan described by Dr. Murray would scarcely recommend itself to surgeons, as its principle was to dilate an opening in order to close it. The plan had been followed in Wutzer's operation for the radical cure of hernia, and had been found to fail.

ON THE DIAGNOSTIC VALUE OF THE ILIO-FEMORAL TRIANGLE IN CASES OF INJURY TO THE HIP, MORE PARTICULARLY OF IMPACTED FRACTURE.

By THOMAS BRYANT, F.R.C.S.

The triangle which the author described as the ilio-femoral, was formed between the ilium and the great trochanter of the femur. One side of it, AB, was drawn from the anterior superior spinous process of the ilium, A, to the top of the trochanter major, B; the second, AC, was drawn from the anterior superior spinous process of the ilium directly downwards to the horizontal plane of the recumbent body; and the third, CB, the base of the triangle, was drawn at right angles to AC, and fell upon the line AB when it touched the great trochanter. To this line the author's observations referred. He said that the line AB corresponded in the normal condition of the hip-joint to Nélaton's test line for dislocation of the head of the thigh-bone backwards, and he regarded the line of the triangle described (CB) to be the test-line for fractures or shortening of the neck of the thigh-bone. He stated that after repeated proofs he could confidently assert that, whilst in a healthy subject the ilio-femoral triangles of the two sides were exactly similar in all cases of injury to the hips, in which shortening of the neck of the thigh-bone existed, the amount of shortening could readily and accurately be made out on comparing the bases of the triangles of the two sides. In impacted fracture, where on the sound side the base of the triangle would, in the adult, measure its average normal length of two and a half inches, on the affected or injured side, it would measure from half an inch to more than one inch less. These measurements were taken with the patient in the horizontal position, the pelvis straight, and the two femora parallel.

The author illustrated his paper by quoting half a dozen cases of impacted fracture, in which by the test-line the shortening in the neck of the thigh-bone was readily made out; and concluded by pointing out the value of such simple and certain means of making out whether any shortening of the neck of the thigh-bone exists after an injury, preventing any undue manipulation of the hip-joint in cases of impacted fracture or other obscure injuries to the joint. He then passed on to point out how fallacies in the test might be met with; but, as they were quite exceptional in practice, he thought that they could in no way tend to diminish the value of the test-line as a means of diagnosis in hip-joint injuries. The paper was illustrated with drawings and a diagram.

Mr. G. POLLOCK asked whether Mr. Bryant did not find equally good results from the old plan of measuring from the anterior superior spinous process to the patella; but he admitted the plan proposed was so mathematically correct that it might be a useful aid in diagnosis.

Mr. THOMAS SMITH said it would be difficult, in a corpulent elderly person, to estimate the position of the trochanter. He had recently been engaged in making measurements on the dead subject; and had found that accuracy could be obtained only by driving a bradawl into the bone. He would prefer the measurement from the anterior superior spine of the ilium (which is readily recognisable) to the external malleolus. The line proposed to be dropped from the spine of the ilium might not be vertical; and it might be difficult to find the position of the trochanter.

Mr. BARWELL said the amount of shortening would be better determined by stretching a tape from the anterior superior spine to the great trochanter than by Mr. Bryant's lines. This plan might be applied in cases of fractures and dislocation. Not unfrequently fractures occurred in thigh-bones which were not accurately alike on both sides, as in old persons who had had rickets. All difficulties here, however, would be removed by measuring through Nélaton's line, rather than from the anterior superior spinous process of the malleolus.

Mr. JOHN WOOD thought a measurement of the kind proposed better than Nélaton's line. He measured, however, from the crest of the ilium to the trochanter; at the same time, in stout females with loose flabby tissue, he combined with it measurement according to the old plan.

Mr. MAUNDER thought that the diagnosis of impacted fracture of the neck of the thigh-bone was well established and very easy. Its signs were negative rather than positive. The limb remained still capable of some motion—which was not the case in dislocation and fracture; but a great point was that, in consequence of the bone being driven into the trochanter, the mass of bone could be felt with the fingers.

Mr. W. ADAMS thought the plan of measurement described by Mr. Bryant likely to be useful in the diagnosis of chronic disease and congenital dislocation of the hip-joint in children. He had used a somewhat similar method, by making dotted lines over the parts.

Mr. CALLENDER said that the late Mr. Stanley had anticipated Mr. Bryant. He used to measure between the different parts by using a flat surface—such as an ordinary prescription board—as the fixed point, in such a way as to ascertain not only the amount of shortening, but of lateral depression.

THE PATHOLOGICAL SOCIETY OF DUBLIN.

At the weekly meeting on Saturday, January 23rd, Dr. HENRY KENNEDY in the chair, the following cases were brought under the notice of the Society.

TUMOUR OF THE LOWER JAW.

The PRESIDENT exhibited a tumour which he had removed from the lower jaw of a boy, 11 years of age, who was a patient in Steevens' Hospital. About fifteen months before admission a tumour commenced to grow at the root of the canine tooth of the left side of the lower jaw. It increased rapidly in size during the last three months, and implicated the right side also. The boy never suffered from any pain, in fact, the tumour was absolutely painless. When admitted the tumour extended almost from one angle of the jaw to the other. The tumour was uniform, and springy to the touch, and some of the teeth were imbedded in it. After it had been removed and a section made they saw a rim of expanded bone filled in with softer material. There was evidently a great expansion of the bone. The anterior and posterior parts were in detachments. Microscopically examined, the tumour presented a remarkably good example of

giant-cell sarcoma, which is a variety of sarcoma consisting of very large cells, which are filled with smaller ones containing nuclei. The patient made a very good recovery.

Dr. E. H. BENNETT brought before the Society an example of

SEVERE INJURY TO THE SCALP ON THE LEFT PARIETAL REGION.

The man from whom the specimen was taken was employed at the Gasworks in Dublin, and while so employed a portion of a windlass, consisting of a beam and an iron block and pulleys, weighing about 30 lbs., fell on him from above, a height of about 34 feet. When admitted to Sir Patrick Dun's Hospital he was unconscious, breathing stertorously, had dilated pupils, and was evidently dying. Half-an-hour after admission he had violent convulsions, and died within an hour. Before death, and while he lay in bed, there was not a sufficient amount of hæmorrhage to require mechanical restraint. On seeing the body next morning in the dead-house a feature showing the gravity of the injury was at once noticed. On the floor there was a great pool of blood which had flowed from a wound in the skull as it lay upon the table rather low. There had been no hæmorrhage during life, nor as far as could be learned in the course of his transit to the hospital. The pool of blood on the dead-house floor caused attention to be directed to the base of the skull as being involved. The case presented an ordinary well-marked depressed fracture, which travelled directly downwards to the base of the skull. There was extensive laceration of the lateral sinuses on the left side. In this case the head had been driven forcibly down upon the spine, which absolutely remained impacted into the cavity of the cranium. One would have supposed that the great weight falling with violence would have rather smashed the skull; but instead of that the force had been transmitted backwards to the articulations of the spine. There was detachment of the posterior clinoid processes, which it was clear was caused in this case by the sudden jerk communicated to the tentorium cerebelli. The interest of the case was, that it showed clear evidence that the fracture of the base of the skull was to be regarded as a fracture by direct violence. He knew of almost only one other instance of an injury coinciding with that which he had now brought under the observation of the Society; that was a fracture by direct violence.

THE SURGICAL SOCIETY OF IRELAND.

The Society met on the evening of the 5th of February, EDWARD HAMILTON, F.R.C.S., Vice-President, in the chair.

Dr. W. HANDSEL GRIFFITHS read a communication on
CERTAIN RECENT THERAPEUTIC REMEDIES,
which will be found at page 158.

The VICE-PRESIDENT said the paper was a valuable one, and he would be glad to hear if any members of the Society had any experience of these new remedies, some of which he thought would prove useful additions to our Pharmacologia.

Dr. EUSTACE could bear his testimony to the value of guarana in the treatment of nervous headache. He had at least a dozen patients taking it. Its physiological effects appeared to be these: For twenty minutes after administration there was remarkable coldness across the forehead, and then the headache abates. The doses varied from half a drachm to a drachm.

Dr. HENRY KENNEDY said he could bear out what had fallen from Dr. Eustace as to the effect of guarana. In three cases in which he had employed it, it decidedly gave relief, but there was this important point about it, that none of the cases had been cured. The drug gave relief at the time, but the pain recurred. The preparation he used was that made up in Paris, and sometimes he gave half a drachm and sometimes a drachm. He could not sit down without lamenting the vast number of new remedies that were now coming forward. It appeared to him that they could do very much more by sticking to some of the old-fashioned remedies than by running after new ones. When he considered the great difficulties that arose in the investi-

gation of any special medicine, testing it by proper experiments and arriving at a correct conclusion, it seemed to him that the addition of new remedies was in some sense to be deplored. They had brought under their notice that night a number of remedies of more or less power, but all the remedies that were mentioned by Dr. Griffiths had had their prototypes. Although he might hear of a new remedy that was believed to be a good tonic, he confessed he would prefer to use the old and good tonics which he had employed before. Dr. Griffiths deserved credit for bringing these remedies before the Society, but it was adding to the difficulty of the whole subject.

Dr. STEWART agreed with the remarks of Dr. Kennedy. He was frightened at the quantity of new remedies that were coming out, and superseding the old ones which were in use when he entered on the practice of the profession. A short time ago, when in the fever ward of the House of Industry, he heard the physician prescribe opium for a patient, and he was delighted to hear of one of the old remedies that he knew being still in use; ipecacuanha was another old remedy of great value, but now it seemed to be neglected. He recollected the practice of the late Mr. Colles, Sir Philip Crampton, and Mr. Carmichael, and he had had a great deal of experience, having been for seven years a dispensary doctor in a large district; but now a lady would sometimes place in his hand a prescription made up of ingredients that he was quite ignorant of. The multiplicity of these new remedies was enough to confound a man of his age and experience.

Dr. QUINLAN disagreed with the gentlemen who objected to the introduction of new remedies. He quite agreed with them that the remedies we have already should never be lost sight of, and that they should receive the most careful study; but it must not be forgotten that medicine was a progressive art, and that when men brought forward new remedies they ought to get a fair trial. Most of the drugs brought forward by Dr. Griffiths he had seen and known of. Most of them would pass into the same place that many new remedies had passed before, but some of them might prove of great value. It must be remembered that some of the old remedies, for example, ipecacuanha, which had been alluded to, were new remedies once, and if they had been thrust aside without a trial, they would never have occupied the position they have now. All new drugs should be tested physiologically, and if they were not found to answer they should be laid aside.

Dr. MONTGOMERY knew the case of a clergyman who experienced great relief from headache by taking guarano in doses of half a drachm on the night before or the morning of the Sunday on which he had to officiate, when he had to perform two or three services. It had been recommended to him by a distinguished physician in London.

Dr. STAPLETON said there was no doubt, as Dr. Kennedy said, that many of these medicines had had their prototypes. He believed the active principle of guarano was theine or caffeine, which was used for nervous headaches. A strong cup of tea or coffee had often been given, and with benefit, for the relief of that affection. He had on two or three occasions given guarano for lumbago, using the French preparation, and giving the doses every two or three hours, and had found a most decided advantage from it. He had used it himself when suffering excruciating pain from lumbago, and got decided relief. Whether it was theine or caffeine he could not say, but it was just like coarse cocoa or chocolate in powder. It was not disagreeable to the taste, and did not cause sickness or loss of appetite.

Dr. DUFFY could add his experience to that of Mr. Stapleton as to the efficacy of guarano in cases of sick headache, with which he was occasionally troubled. He had taken it himself with most beneficial results, and had given it with great advantage to ladies similarly affected. The preparation he used was Grimond's, a dose being made up in one package.

Dr. STAPLETON: It is not fair to say that guarano does not cure, for there is no medicine I know that can cure anything save sulphur for itch.

Mr. H. GRAY CROLY thought the paper was one of great interest to the Society, and that Dr. Griffiths deserved credit for the trouble he had taken in bringing these new medicines under their notice. It was a weak thing to stand up and condemn drugs because they were new. Was there any practitioner who would like to give up hydrate of chloral? It was a new drug, and had filled a gap long existing, and if any of the medicines mentioned by Dr. Griffiths filled a similar place, it would be the addition of a new and valuable drug.

Dr. Griffiths ought to be encouraged to persevere in his inquiries and to bring new drugs under their notice, and let the members sift them and ascertain their real value. He had known cases where chloral had proved a blessing to the patient, where morphia disagreed with the individual, and chloral was found to be an effectual substitute, and that drug had now taken a permanent place in our list of medicines.

Dr. BENSON: Nothing delights me more than to hear of these new remedies. Many of them are extremely valuable; and I have myself used podophyllin with very great advantage. Were not all the remedies that have ever been used in the practice of medicine new at one time? We might as well object to the use of the stethoscope, and indeed I remember, shortly after its introduction into this country, that it was ridiculed as a "pot-stick" by an eminent member of the medical profession, and even openly ridiculed by men of eminence in their clinical lectures. There is hardly any remedy which can be introduced which may not prove beneficial if followed up with care and its effects carefully studied. Even old remedies are now used in a new point of view. We use digitalis in a different form than formerly when we employ it as a stimulant of the heart. When we used to say "we will bring down the pulse in such a time by digitalis," it did not prove that the drug may not have been a stimulant in the first instance. So likewise belladonna, once called the opium of the heart, is now known to have a different effect. New remedies are constantly coming forward, and it appears to me extremely wrong to limit the introduction of them when they are used with care and judgment by men of experience and good sense. We ought to be grateful to any one who introduces them, and any gentleman who brings them under our notice deserves our approbation. Every man to the last period of his life must be always learning. We are all students to the end of our days, and I delight to come here to learn something, even though I can never make use of it afterwards.

Dr. QUINLAN read a communication on

A METHOD OF CURING SOME OF THE CONTRACTIONS IN THE NEIGHBOURHOOD OF JOINTS THE RESULT OF BURNS AND SCALDS,

which will be found at page 160.

In the succeeding discussion the VICE-PRESIDENT said: Anything that gives us assistance in dealing with these cases is valuable, for we all regard them as a sort of opprobrium of surgery, being very difficult to manage, and often most unsatisfactory in their results.

Dr. STAPLETON said there was no doubt these cases were extremely difficult to manage. Years ago the same thing Dr. Quinlan proposed used to be done in these cases. Not only the unsound but the sound part was perforated with a lead wire, which was left in until the part healed round it, and then the wire was gradually twisted until it went through. He had done that in several cases where the hands were affected. They seemed for a time to be going on well, but did not turn out satisfactorily. A case was sent to him from the country where the hand was bound, and there was a cicatrix on the anterior and posterior folds of the axilla, but the muscles there had got such perfect power that the patient, a girl, was able to put her hand to her head and her back; therefore, he did not think it right to perform any operation. Some years ago a girl was brought to him with a burn on her forehead. Her upper eyelid was destroyed. He performed an operation, bringing down a long flap, and passing a ligature through the lower eyelid. Mr. Ellis, who was present, said, "I think you will have to perform another operation to bring it up into its proper place." Everything was going on well; the eyelid seemed to be everything that could be wished for. He was obliged by illness to go abroad, and during his absence the girl was kept in the hospital as a kind of show, to let people see what a beautiful operation it was; but when he came back he would have been glad if they had sent her away, for her eyelid was as high up as ever. Thus it was hard to say how these operations would ultimately turn out. The only effectual proceeding in his opinion was removing the cicatrix entirely and performing a plastic operation.

Dr. WHEELER said he had had some of these cases of contraction under his care, and he could not agree with Dr. Quinlan in thinking that the new operation he had proposed in cases over the knee and foot and shoulder would be preferable to Esmarch's bloodless operation and the removal of

the cicatrix by the knife. Three years ago he had a case of dislocation of the wrist caused by the contraction of a burn. He removed the cicatrix, and although it was two years and seven months since the operation, it had not contracted, and the individual had got perfect power over the hand. He thought the removal of the cicatrix by the knife caused much less pain to the patient than the plan proposed by Dr. Quinlan, and he believed also that Esmarch's apparatus produced local anaesthesia.

Mr. H. G. CROLY said he thought it was a great pity that such cases should occur at all. They knew that when cases of burns at the bend of the elbow or on the neck were met with in hospital and treated with ordinary care, they did not turn out patients with their arms tied up or otherwise deformed. He had operated in one case where a child's eyelid was turned inside out. He knew perfectly well what would happen, and, as he anticipated, the result was not satisfactory; but he prepared the friends of the patient by telling them that in his opinion, when the child got a little older, the eyelid would be as bad as ever. He operated recently on a soldier's child, where the chin was tied down to the sternum. He had a troublesome operation by dissecting the skin from off the sternum, and by prolonged care and treatment the child was greatly improved, but there was still a certain drag. The last case he had of this kind was still under treatment. A little girl was sent to hospital with her arm bound up at a right angle to the body. He used Esmarch's bandage, and dissected away the entire silvery cicatrix that was visible and fixed the limb in a splint. He had also determined to try skin-grafting in this instance, and he trusted that by putting new tissue where the silvery cicatrix had existed, the cure of the case would be facilitated. Esmarch's bandage was only available in cases of the extremities, the legs and arms, and could not be used in the axilla or the neck.

Dr. P. LITTLE considered that Dr. Quinlan deserved the thanks of the Society for bringing forward a new method of treating cases of this kind. He had had an opportunity of observing the results which had followed the treatment of cases of severe burns in the City of Dublin Hospital. He had seen the case mentioned by Dr. Wheeler, and was much gratified at the result of his operation, and approved of the measures he had adopted. Dr. Quinlan's case seemed to be satisfactory, and when contraction was caused in the axilla by burns it might be used with benefit, but it had no advantage over the old system of lead suture.

Dr. QUINLAN, in reply, said the case described by Dr. Stapleton differed from the one he had brought forward in this respect, that in the former the arm was brought out almost at right angles, whereas in his (Dr. Quinlan's) case it was brought out only two and a half inches. In that case interference was necessary, but Dr. Stapleton exercised a wise discretion in leaving his case alone. In his case the cicatrix was very large; it existed on the side of the arm and on the chest, and especially in the axilla. He had thought of removing it, but was afraid that in the contracting process the axillary veins might have been removed, and that in trying to take away the cicatrix he might have got into trouble with the axillary vessels. Mr. Croly's suggestion as to skin-grafting was a valuable and practical one. He had been in the habit of using skin-grafting with good results in the cases of old ulcers where the vitality of the edges had become exhausted, but he had never tried it in the cicatrization of burns. He thought it would be a useful proceeding, and it was certainly worth trying whether the new tissue thus formed would be as contractile as the old. He was fully sensible of the danger of the return of the contraction, and if the patient came to him a year hence as bad as he was before the operation, he would regret it, but would not be in the least surprised. However, after twelve months the case had proceeded satisfactorily up to the present. He thought the method he had brought under the notice of the Society was worthy of a trial. It was free from pain and risk, and was extremely simple.

The Society then adjourned.

On his retirement from practice in Barnsbury, where he had resided for thirty-eight years, Dr. Ede was, last week, presented with a handsome silver salver and a cheque for £191, which had been subscribed by patients in testimony of their esteem of his character and skill.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, FEBRUARY 24, 1875.

THE DUBLIN HOSPITAL SUNDAY DISTRIBUTION.

In our last issue we referred in general terms and in a disapproving tenor to the system which had been adopted for the distribution of the Hospital Sunday Fund in 1874, and which it is proposed to perpetuate in 1875. We protested against the continuance of a method of allocation which has, admittedly, acted most partially by giving an excessive share to “subscription” hospitals, which has utterly ignored one of the largest and most useful fields of hospital work—viz, extern relief, and which has squandered the sparing contributions of the benevolent persons upon redundant officials, to the great injury of the sick poor themselves.

We revert to the question now for the purpose of putting before our readers in detail the facts upon which we have based our opinion, and which must, we believe, lead them to a concurrence in our view. It was, as our readers remember, part of our objection to the system that two-thirds of the entire fund were handed over to hospitals in proportion to the amount of their private subscriptions, without any reason for such a division, except the bare fact that these hospitals received a portion of their funds from private benevolence. For this reason the City of Dublin Hospital received no less than £1,160—more than one-third of the entire fund, while Mercer’s Hospital received only £387, and if the Adelaide Hospital had co-operated, it would have received £668, whilst Mercer’s would have been given only £245.

The following are the figures relating to the four general hospitals which participated in the grant:—

	Subscriptions, Donations, and Charity Services.	Amount of Grant.
City of Dublin - - -	1,822 6 0	1,160 17 2
Sir Patrick Dun’s - - -	598 2 8	335 17 5
Mercer’s - - -	597 2 11	387 18 10
Stevens’ - - -	477 6 0	312 0 4

We do not for a moment infer that the City of Dublin Hospital is undeserving of this money; but, on the contrary, we are aware that no institution in Dublin does

better or larger work for it subsidy, and the feeling of all those interested is with us in this expression of opinion; but we protest against its receiving a third of the entire fund—not because it did good work—not because it did that work economically, but simply because it was situated in an opulent neighbourhood, and managed by active men who have a close personal stake in its success, and therefore enjoys the largest amount of personal favour amongst Dublin hospitals. It would have received the same sum if it had been the worst managed and most expensive institution.

Amongst medical men there may be an idea that hospitals which receive a Government subsidy should not enjoy the same amount of support from the charitable purse; but we entirely dissent from this view. We have already said that “the public, from whose pockets the charity comes, care nothing about the source from which the income of an hospital is derived. They are anxious only that what they give shall bring the greatest benefit to the sick poor, and that the least proportion of it shall go in other expenses; and we believe that the system adopted for the last distribution affords no such guarantee.”

The equitable and business-like course would be to hold every hospital responsible to show a given quantity of work in proportion to its total income. Thus, if Hospital No. 1 possessed a gross income of £5000 a year, and Hospital No. 2 a gross income of £1000, no matter from what source derived, and if the standard cost of yearly maintenance of a bed in a well-managed hospital were found to be £50, it would be incumbent on No. 1 to show that it had maintained 100 beds, and No. 2 only 20. Thus the enjoyment of a large public grant by No. 1 would have no material influence on its share of the fund, and if it appeared that No. 1 only maintained (say) 75 for its £5000, and that No. 2 maintained (say) 25 for its £1000, the assessment of a share to the former should be proportionately less *per bed maintained* than to the latter. There are, of course, other minor elements in the consideration, but it seems to us that this course would be the just one to all institutions, and we submit again, in the strongest terms, that the public who give the money have a right to see that it will be apportioned to hospitals not because they have or have not a Government subsidy, but because, if they have, they do sufficient good work in return for their income.

The exclusion of extern work of an hospital from the calculation of a share in the fund is the second point against which we argued in our last issue, and a perusal of the statistics published by the Fund Council appears to us to justify completely our protest on this score. Of the relative proportion of extern work done by the various hospitals we have no returns, because the Council have not asked for such information, but it is well known that there is the greatest difference between different hospitals in this respect, some of them being restricted in their out-door usefulness by circumstances of locality, and others being largely resorted to because they are the fashion with the sick poor. Let us again compare two given hospitals, A. and B., from this point of view. A. is an extensive building with abundant funds and a large clientele of subscribers. B. is a small hospital in a poor locality, with a comparatively small income. At the

dispensary of A. few present themselves, and those who do so may be the retainers of my Lady Bountiful, who subscribes her guinea a year for the sake of recommending twenty guineas' worth of patients to its wards. We appeal to the experience of the profession in Dublin whether the wards of such an hospital are not half-filled with chronic coughs, rheumatic joints, minor accidents and so forth, because there is plenty of room for all comers, and plenty of money to support them in the house. How different is the case of Hospital B. The dispensary of this hospital is crowded with patients—pneumonias from exposure, machinery accidents, broken arms, and all the usual run of cases contributed by a closely-packed neighbourhood of artisans. But the hospital has little room and little money, and therefore no case which can be possibly left at home is admitted. Nevertheless, the work done by the hospital is constant and exhausting upon its resources, and it dispenses in its neighbourhood perhaps ten times as much real useful relief as does Hospital A.

How do these institutions fare respectively in the sharing of the Fund? Hospital A. produces a great crowd of intern cases and receives a large dividend, while Hospital B., though it has probably administered five times the quantity of relief, gets almost nothing.

The returns of the Council inform us that though the City of Dublin Hospital got credit for no extern accidents at all, nor any extern midwifery cases, yet it received £408 for its "work done," while Mercer's, which presented a record of 2,182 extern accidents, received only £141, Steevens', with its 1,466 accidents and 105 extern midwifery cases, only £114, and Sir Patrick Dun's, with 624 accidents and 523 extern midwifery cases, only £88.

For their vast work amongst the extra-hospital poor Mercer's only received credit for 2'18 beds, Steevens' 1'67 beds, and Sir Patrick Dun's 1'68 beds. In fact, as far as participation in the Fund goes, these hospitals would have been just as well without their extern departments.

We submit it to the judgment of the Council whether the adjustment of claims is on these grounds just, or calculated to give confidence to the public in the management of the Fund. We shall add something more next week to what we have already said.

VEILED OBSCENITY.

THE rascality of the obscene quacks, and the publicity which a few of their more flagrant misdeeds have received through the medium of the police reports have to a certain extent counteracted their pestilential influence in society. With what we know of these medical swindlers before him, a man must be an irredeemable fool or a filthy-minded valetudinarian who answers their obscene advertisements, and it is perhaps hardly to be regretted if such persons meet with the victimization which they deserve. But the ingenuity of these rascals is great, and finding that no decent being will read their dirty advertisements, or have anything to say to them, they have recourse to a *ruse* which at the same time obtains insertion of their advertisements in respectable news-

papers and brings them into immediate communication with the class of persons whose money they covet.

In a Dublin morning paper of the highest character we find the following advertisement:—

EMPLOYMENT.—I want 1,000 Agents to Canvass for "The Complete Herbalist." I will give such terms and furnish such advertising facilities that no man need make less than £30 per month and all expenses, no matter whether he ever canvassed before or not. A premium worth half a guinea given to Lady Canvassers. Address Prof. O. Phelps Brown, ———, and full particulars will be sent by return of post.

We may picture to ourselves the hopeful haste with which young men and women anxious for some paying employment, sent in their applications for the "particulars" which promised over £300 a year (and a half-guinea bounty for lady canvassers) to all of them, skilled or unskilled. We, without any intention of embarking in the speculation, applied for the "particulars." We received a pamphlet which purported to be a prospectus and table of contents of "The Complete Herbalist," but which was, in fact, a disgustingly indecent trap for the unwary and the prurient—a *vade mecum* of all the beastly immoralities which are the speciality of such scoundrels as Professor O. Phelps Brown. We would not be understood if we refrained from printing a few of the head-lines. We are told of the contents of the book that—

"It gives the marriage customs."

"It gives all the laws that should regulate sexual commerce."

"It gives a view of the inner life between husband and wife."

"It gives all the causes that usually tend to marital infelicity."

"It gives all the precautions to be observed by both male and female before entering the marriage bond."

"It gives the positive faults of either candidate."

"It teaches how to prevent conception in justifiable cases."

"It teaches the fallacies committed by both husband and wife in their relations."

"It teaches the customs of sexual association from the primitive condition of man to the highest civilisation."

These and many more obscenities of the sort are carefully interspersed amongst the contents of the book referring to hygiene, diets, and medicine, so that the unwary may not discover the character and object of the book until they have taken in the poison of its immorality.

We blush for the necessity which obliges us to transfer such obscenity to our columns, and we ask whether it can be said that a public prosecutor is unnecessary when the punishment of such villany is left to the individual victim? Finally, we are told that "the Press throughout England are unbounded in their laudations of this work," and that "a superior drawing-room edition is now ready, in morocco cover," and that it contains profuse illustrations of "the organs of the human body."

We are aware that the journal in which we found the advertisement was entirely unconscious of its character, and on being informed on the subject at once stopped the advertisement; and we hope—now that we have publicly stated the character of the "employment" which is offered—that the announcement will be promptly drummed out of the columns of all respectable papers.

THE ACTION OF DRUGS.

X.

We have now arrived at the conclusion of our analysis of the Report of the Committee of the British Medical Association upon the antagonism of drugs; but before leaving the subject, we are desirous of calling the attention of our readers to the main object we had in making the analysis, and this we purpose doing by giving a *résumé* of those portions of the Report which we consider are of practical value, not only to future experimenters, but also to the scientific therapist in his daily practice.

Upon referring back to our first Article (MEDICAL PRESS, Nov. 4, 1874), which was devoted to the analysis of the Committee's report upon the antagonism existing between hydrate of chloral and strychnia, we observe that their experiments prove the following points:—

(1) That 21 grains of chloral hydrate is the minimum fatal dose for a rabbit of 3 lbs. weight.

(2) That 1-96th of a grain of strychnia is the minimum fatal dose for a rabbit of 3 lbs. weight.

(3) That to a certain extent chloral hydrate modifies the action of strychnia, and under certain circumstances may antagonise a fatal dose of that drug, by depressing the excess of reflex activity of the spinal cord induced by strychnia, and reducing the frequency and force of the tetanic convulsions.

(4) That strychnia may mitigate the effects of chloral hydrate upon the spinal cord by rousing its activity, but is powerless so remove the coma due to the action of the chloral upon the brain.

In Article 2 (MEDICAL PRESS, Nov. 11) the report upon the antagonism between Calabar bean and sulphate of atropia was considered, and the main points of interest adduced were as follows:—

(1) That 20 to 21 grains of sulphate of atropia is the minimum fatal dose for a rabbit of 3 lbs. weight.

(2) That 3-4ths of a grain of extract of Calabar bean is the minimum fatal dose for a rabbit of 3 lbs. weight.

(3) That for all practical purposes, atropia, as an antidote of Calabar bean, is useless.

(4) That while Professor Bennett states that with 4 to $\frac{1}{2}$ grains of atropia no symptoms were produced in rabbits, other experimenters find 1-48th to 1-24th of a grain produces physiological effects in a dog, 1-12th of a grain affects a horse, and 1-120th to 1-96th of a grain is sufficient to affect a man.

(5) That when more than a fatal dose of extract of Calabar bean—viz., gr. $1\frac{1}{2}$, was followed by a dose of atropia, stated to be far too small to produce any physiological symptoms (viz., $\frac{1}{2}$ of a grain) by itself, yet life seemed to be prolonged; and in Experiment 169, $\frac{1}{2}$ of a grain of extract of Calabar bean was successfully antagonised by $\frac{1}{2}$ of a grain of atropia.

(6) That we pointed out that this result was due to the stimulant action of small doses of atropia upon the heart, and that when the dose of atropia was increased the tendency was to a rapid fatal termination, as a large dose depresses the action of the heart (as was found to be the case). It is unnecessary to recapitulate our remarks on this point.

In Article 3 we had under consideration the antagonism

between extract of Calabar bean and hydrate of chloral. The results of this investigation are thus summarised by Professor Bennett:—

1. Hydrate of chloral modifies to a great extent the action of a fatal dose of extract of Calabar bean, mitigating symptoms and prolonging life.

2. Hydrate of chloral in some cases saves life from a fatal dose of extract of Calabar bean.

3. If hydrate of chloral be given before extract of Calabar bean, so that the animal is deeply under the influence of hydrate of chloral before it receives the extract of Calabar bean, the symptoms produced by the latter are much modified, and life is saved from the effects of what would otherwise be a fatal dose.

4. Chloral hydrate is of little service as an antagonist to extract of Calabar bean, if given some time after the latter. If the symptoms of the action of Calabar bean be in full operation, it will not save life, however it may modify symptoms.

5. The antagonism is limited—

a. *By the amount of dose of the extract of Calabar bean*—more than a minimum fatal dose of extract of Calabar bean destroying life, notwithstanding the administration of chloral hydrate.

b. *By the interval of time between the administration of the two substances.* There is a great probability of saving life in those instances in which the animal is under the influence of chloral hydrate before the subcutaneous injection of the extract of Calabar bean; there is less probability when both substances are given simultaneously; there is still less if the chloral hydrate be given from five to eight minutes after the extract of Calabar bean; and no chance at all if the chloral hydrate be given eight minutes after a fatal dose of extract of Calabar bean.

6. Even in cases in which a fatal result follows the action of the two substances, the physiological effects of extract of Calabar bean are considerably modified by those of hydrate of chloral.

We then called attention to the statement in the report that there was no chance of recovery after a fatal dose of extract of Calabar bean if the chloral hydrate be given *more than eight minutes* after, and naturally inferred that chloral would not be of much practical value in the treatment of a case of poisoning by Calabar bean, the more so as we have every reason to believe that the chloral does not commence to act on the system till decomposed into chloroform and formic acid, whilst the Calabar bean commences to affect the system almost immediately upon introduction. The experiments, however, showed that chloral modified the action of the Calabar bean; therefore we might use chloral in conjunction with other remedies. The experiments with hydrochlorate and meconate of morphia and Calabar bean alluded to in the same article showed that no antagonism existed between these drugs; the experiments, however, served to prove that twelve grains is the minimum fatal dose of hydrochlorate of morphia for a rabbit of 3 lbs. weight, which, in itself, is curious, as we know that a dose of one to two grains of morphia has killed a man, while thirty-six grains have been given to a horse without a fatal result. This difference in the dose required to produce certain effects in various animals should be borne in mind by experimenters. Another interesting point to which we drew attention was that, in Experiment 275, a rabbit weighing 4 lbs. recovered after a dose of *thirteen* grains of hydrochlorate of morphia; yet in Experiment 293 a rabbit of the same weight died within seventeen minutes after receiving *three* grains of the morphia fol-

lowed in six minutes by 2-3rds of a grain of extract of Calabar bean.

In Article 4 (*MEDICAL PRESS*, Nov. 25, 1874) the report upon the antagonism between sulphate of atropia and meconate of morphia is discussed, and Professor Bennett thus sums up the results of this investigation:—

A. In Rabbits:

1. Sulphate of atropia is physiologically antagonistic to meconate of morphia within a limited area.

2. Meconate of morphia does not act beneficially after a large dose of sulphate of atropia, for in these cases the tendency to death is greater than if a larger dose of either substance had been given alone.

3. Meconate of morphia is not specifically antagonistic to the action of sulphate of atropia on the vaso-inhibitory nerves of the heart.

4. The beneficial action of sulphate of atropia in cases of poisoning by meconate of morphia is probably attributable to the action which the former substance possesses of contracting the blood-vessels, and thus diminishing the tendency to cerebral and spinal congestion produced by salts of morphia.

B. In Dogs:

Sulphate of atropia modifies the physiological action of meconate of morphia, and may even save life after a fatal dose of the latter. The limit, however, is so narrow as to be of no practical service.

In addition, however, we directed the notice of our readers to the following points of interest:—

(1) That Experiments 301, 302, 303 indicate that in rabbits under the influence of morphia the sciatic nerve responds to stimulus; also if the vagi be exposed and stimulated by the induction current, total stoppage of the heart's action follows; also if the sympathetic nerve is stimulated, contraction of the pupils follows.

(2) That marked physiological effects are produced by two to three and a-half grains of morphia in a dog, while seven to eight grains may be given to a rabbit without producing any more marked effects than drowsiness, contraction of pupils and slight spasms (Experiment 284); and that although in both animals the effect is upon the encephalon and spinal cord, the action is in dogs more cerebral, while in rabbits it is more spinal.

(3) That morphia neither destroys the sensibility and conducting power of the nerves, nor does it paralyse the vaso-inhibitory fibres with vagus or the sympathetic.

(5) That while about 20 grains are given as the minimum fatal dose for a rabbit, only $\frac{1}{2}$ of a grain is found sufficient to produce fatal results in a dog.

(6) That atropia does not paralyse the motor nerve tubes, but that it does paralyse either the trunk of the cardiac branch of the vagi, or the intrinsic nerve centres in the heart, with which the cardiac branches are connected.

In Article 5 (*MEDICAL PRESS*, Dec. 9th, 1874) we first quote a letter from Dr. W. A. Richards, of Winchester, commenting on the minuteness of the dose of atropia used to antagonise a fatal dose of extract of Calabar bean, and asking for an explanation. This explanation we have given, and at the same time we called attention to the fact that Dr. Lauder Brunton recommended 1-100th of a grain of atropia as an antidote to a fatal dose of muscarine, and we also took the opportunity of commenting upon the dual action of drugs, which serves to explain seeming discrepancies in the results arrived at by various experimenters.

Next the views of Dr. Harley, and Messrs. Mitchell, Keen, and Morehouse, as quoted by Professor Bennett, are contrasted. The experiments conducted by the Committee prove that morphia lowers considerably the cardiac impulses and the respiratory movements. Although the American physicians say that the drug lowers the pulse slightly, or not at all, they also state that the nausea of morphia is not antagonised by atropia; this our own clinical experience contradicts, and we are sure we are not alone in believing that atropia does, in doses of 1-100th to 1-80th of a grain, antagonise the nausea of morphia; although we believe with Dr. Harley that atropia alone is *decidedly* not an *antidote* to morphia, but still may be useful in cases of poisoning by opium (in doses of 1-96th of a grain), to stimulate the failing power of the heart, and thus, in conjunction with other remedies, promote recovery.

In Article 6 (*MEDICAL PRESS*, Dec. 16th, 1874) we continue our remarks upon atropia and morphia, and now we have dogs as the subjects of experiment. Notwithstanding that in Experiments 308, 309, the animal recovered after receiving 2½ grains of morphia and 2-3rds of a grain of atropia, we would be reluctant to treat a case of poisoning by morphia in the human subject by atropia alone. We have already placed on record our objections to the conclusiveness of these experiments.

In Article 7 (*MEDICAL PRESS*, Dec. 28, 1874) we have under consideration an entirely new series of experiments to ascertain the antagonism between tea, coffee, theine, caffeine, guaranine, on the one hand, and meconate of morphia on the other, and we cannot do better than give Professor Bennett's conclusion in his own words:—

1. Theine is antagonistic to meconate of morphia, inasmuch as the action of the one substance modifies that of the other, and may even save life from a fatal dose of either substance.

2. Meconate of morphia delayed the appearance of the convulsions characteristic of the action of theine; but, on the other hand, theine, if given in large doses, did not affect in a marked degree the action of meconate of morphia, because symptoms of poisoning by theine were soon manifested.

3. Further experiments on cats showed that, (1) while a cat may recover from the effects of a dose of 1½ grains of meconate of morphia given alone, it will not recover from the effects of a dose of 2 grains, even although the effects of the latter dose are modified by those following the introduction of 4 and 5 grains of theine; (2) that in three cases the animals recovered from the effects of 1½ grains of meconate of morphia and 4 to 5 grains of theine, while they died when the same dose of meconate of morphia was administered eight days afterwards; (3) that when the dose of theine was increased beyond five grains, the animals invariably died, apparently from the effects of theine.

4. Experiments on rabbits, as to the antagonism between meconate of morphia and theine, were found to be unsatisfactory as regards the purposes of this inquiry, because both drugs produce epileptiform convulsions in these animals.

5. The results obtained in investigating the action of caffeine and guaranine as antagonists to meconate of morphia were similar to those observed with reference to theine.

6. Experiments were made on dogs to ascertain the effects of strong infusions of tea and decoctions of coffee as antagonists to meconate of morphia. These were unsatisfactory, chiefly because the tea or coffee was usually vomited so soon as to prevent the possibility of the exar-

cise of any physiological antagonism. At the same time, it was observed in several instances that the administration of tea or coffee so excited the animals as to prevent them from falling into stupor or coma after a dose of meconate of morphia, which would have produced this effect had the tea or coffee not been given.

The points of interest in this portion of the Report are—

(1) The remarks upon the physiological action of cocaine and extract of coca, to which we refer our readers.

(2) The effect of cocaine, theine, and caffeine on the respiration, cardiac pulsations, and temperature.

(3) We called attention to the fact, that while the Committee found the three drugs alluded to above tended to raise the temperature above the normal, other experimenters (Messrs. Burness and Mavor, "Specific Action of Drugs") had found various drugs to produce the same effect when administered to an animal in a healthy condition—for example, datura tatula, acetate of morphia, atropia, opium, and bichromate of potash, which last-mentioned drug raised the temperature in a horse from $100\frac{1}{2}^{\circ}$ F. to $106\frac{3}{4}^{\circ}$ F. This point we consider worthy of further investigation.

The chief points elucidated by the concluding experiments of the Committee, and contained in Article 8 (MEDICAL PRESS, Jan. 20, 1875), are the following:—

(1) That the action of theine on the cat is more marked than on the rabbit, intense excitement being produced in the former animal; the minimum fatal dose for a cat weighing 5 lbs. being $5\frac{1}{2}$ grains, and for a rabbit weighing 3 lbs. 4 ozs. about the same quantity.

(2) That the minimum fatal dose of meconate of morphia for a cat was found to be $1\frac{1}{2}$ to $1\frac{3}{4}$ grains; but in addition the experimenters observed that *small* doses of this drug produced dryness of the mouth, while *large* doses produced *salivation*. We have here another instance of the dual action of drugs.

(3) That the minimum fatal dose of caffeine for a cat of about 5 lbs. is 6 grains, and that the effects produced are similar to those following the introduction of theine.

(4) That theine produces intense cerebral excitement, associated with gradual loss of the functions of the spinal cord.

(5) That the Committee failed to determine the extent of the antagonism between infusion of tea and morphia, as the morphia being first introduced subcutaneously, produced so much nausea that the infusion of tea, when introduced into the stomach, was almost immediately rejected. Probably better results might be obtained if the infusion of tea were injected into the rectum.

The Committee conclude their report with the experiments as to the antagonism between (1) Strychnia and extract of Calabar bean; (2) Bromal hydrate and atropia. The results of these investigations were—

As to the antagonism between extract of calabar bean and strychnine.

Although the symptoms produced by either substance were modified considerably by the action of the other, there was no instance of recovery from a fatal dose.

As to the antagonism between bromal hydrate and atropia.

1. There is a distinct physiological antagonism between bromal hydrate and atropine.

2. After a fatal dose of bromal hydrate, the introduction of atropia arrests excessive secretion from the salivary glands and mucous surfaces of the lungs, and thus obviates the tendency to death from asphyxia caused by the accumulation of fluids in the air-passages. Atropia also causes contraction of the blood-vessels, and thus antagonises the action of bromal hydrate, which causes dilatation of these vessels by paralysis of the sympathetic nerve.

3. While atropia may save life after a fatal dose of bromal hydrate, the converse apparently does not hold good, as we have never succeeded in saving life after a fatal dose of atropia by the subsequent injection of bromal hydrate.

In addition we indicated the following points of interest:—

1. That nearly fatal doses of strychnia are not antagonised by nearly fatal doses of extract of Calabar bean, and *vice versa*.

2. That 4 to 5 grains of bromal hydrate is sufficient to kill a rabbit weighing 4 lbs.

3. That bromal hydrate acts more on the ganglia at the base of the brain and on the spinal cord (and less vigorously on the hemisphere), the animal frequently dying in a state of opisthotonos.

4. That the physiological action of iodoform was determined (*vide* Article 9).

5. That the extremely small dose of 1 to $1\frac{1}{2}$ grains of atropia was found sufficient to antagonise the fatal dose of 4 grains of bromal hydrate.

We have now completed our analysis of the report of the labours of the Committee. We are sure the profession must feel deeply indebted to Professor Bennett and the several members of the Committee both for the able manner in which they have conducted these numerous experiments and also for the clear manner in which they have placed the results before the medical public.

If we have succeeded in awakening an interest in the subject which the Committee have been so patiently investigating, and if our remarks have drawn attention to those points which we consider they have failed to decide, and stimulated others to the work, we will feel satisfied.

We cannot do better than quote here Professor Bennett's concluding remarks, with which we entirely agree:—

"I venture, however, to say that such are the toils and sacrifices required by modern medicine, if it be sincerely desired to solve existing difficulties, and prosecute those new inquiries which are so necessary for maintaining its position as a science and as an art. I sincerely trust that no parsimony nor error in administration will restrain the British Medical Association from continuing the noble efforts it has commenced, and rewarding by liberal grants the arduous labours of men who will dedicate themselves to these pursuits. It is gratifying to know that the present, and it is to be hoped, the future flourishing state of its finances, will enable it to take a lead in this patronage of scientific and practical endeavour for the benefit of humanity. I shall always esteem it a proud distinction for myself that I first indicated at least one method in which this could be accomplished, and have demonstrated, in the two reports I have had the honour of laying before the Association, on the one hand, how error may be corrected, and, on the other, how new fields may be acquired for the therapist in neutralising poisons and extending our means for the cure of disease."

Notes on Current Topics.

The Combined Administration of Chloral, Morphia, and Atropia.

DR. BARTHOLOW (*The Clinic*, Jan. 2) says that the great mass of narcotic remedies are administered conjointly without an adequate conception of the part which each one plays in the results produced. Thereupon he made some experiments chiefly by means of the hypodermic syringe. One drachm of chloral to four of water gives a solution of sufficient density, and 30 minims contain seven and a half grains. Into this solution was put one grain of sulphate of morphia, and into another solution was put six drachms of chloral, four grains of sulphate of morphia, and a quarter of a grain of atropia sulphas in two ounces of water.

A solution of chloral injected under the skin causes a smart burning sensation, lasting from five to fifteen minutes, and usually leaving an induration which slowly disappears. This does not, however, seem to tend to suppurate. Absorption quickly takes place, for chloral being a crystalloid, diffuses easily into the blood. It causes a feeling of frontal distension, some headache, and vertigo, and drowsiness, supervening in from ten to twenty minutes, like that produced when chloral is taken by the mouth. One-fourth to one-half the quantity necessary to produce sufficient effect is required by the subcutaneous areolar tissue as compared to stomach administration; and when combined with morphia and atropia the quantity required need be very small.

Chloral and atropia do not act on each other chemically. Rabbits bear chloral very well indeed, but they are rather unsusceptible to the action of atropia when taken into the stomach, whilst the hypodermic injection of the drug is followed by the usual physiological effects. Atropia prolongs the chloral narcosis several hours. Thus, a rabbit to which Dr. Bartholow gave twenty grains of chloral subcutaneously remained in a state of narcotism six hours; when one grain of atropia was added, the narcotism lasted eight hours. In various observations he made on himself with chloral and atropia combined, Dr. Bartholow observed the following fact: That the excitant action of the atropia hindered the occurrence of the chloral narcosis, but sleep usually ensued after two hours, and was always profound. On the following day the pupils were dilated, the mouth dry, and there was more or less giddiness and headache. These effects were produced by eight grains of chloral and 1-94th of a grain of atropine. The effects of atropine continue much longer than those of atropia.

With regard to chloral and morphia, the latter substance in the rabbit deepens in every way the effect of the former. On his own person, Dr. Bartholow found that when he took morphia alone there was a great deal of discomfort produced—nausea, vomiting, vertigo, headache, and wakefulness. When combined with chloral, the nausea and vomiting are lessened, but not prevented, and sleep is produced. Chloral does not prevent the unpleasant after-effects of morphia—nausea, loss of appetite, constipation, headache, and vertigo—for these symptoms are experienced on waking from the chloral-sleep.

Those who bear morphia well are also favourably affected by a combination of chloral and morphia, but in man as in rabbits, morphia increases in the whole sphere of its influence the chloral narcosis. As, however, morphia is synergistic to chloral, a dose of the latter far short of lethal activity will be sufficient in most cases when the former is combined with it.

A combination of chloral, morphia, and atropia presents the greatest advantages from the physiological and therapeutical point of view. Dr. Bartholow has made numerous experiments on his own person in this matter. Chloral causes sleep, morphia relieves pain, and atropia prevents or lessens the depression of the heart and respiration caused by the agents associated with it, whilst it certainly contributes to the cerebral effects of both. He found that the action of the combination was much more agreeable than chloral or atropia or than chloral and morphia. Sleep followed more promptly, without being preceded by nausea and excitement, and the after-effects were either absent or slight.

Practical Conclusions.—Dr. Bartholow hence concludes that the combination of chloral, morphia, and atropia, in the relative proportions he advises, used subcutaneously or by the mouth, is extremely well adapted to the treatment of insomnia in certain of its forms. In all cases in which pain is an important factor in the causation of wakefulness, the combined action of chloral, morphia, and atropia is much more effective than either agent alone. He cannot too strongly urge this combination in cases of insomnia in the subjects of fatty and dilated heart, and in the irritable heart of the chronic smoker. The combination of chloral and bromide of potassium is ill-advised in such cases. When a suspicion of heart disease exists, it were better to use morphia and atropia than chloral alone.

Pain.—For the relief of pain, says Dr. Bartholow, no one denies that the hypodermic injection of morphia is the most effective agent we possess. On the score of propriety and safety some persons object to it. The hypodermic injection of chloral, morphia, and atropia, barring the greater pain it gives, is more agreeable in its effects, and it seems to him, more permanent in its result. He has used this combination in neuralgia of the fifth of the brachial plexus, of the lumbar nerves, of the sciatic nerve, and coccygeal nerves, and about the seat of the painful spinal points in visceral and other neuralgias, and in spinal irritation. Whatever may be said in its favour, the remote injection of anodyne for the relief of pain is not so effective as application to the painful points. It is familiar to all how, when the parts swell about a painful nerve, the pain ceases.

The effects of irritant injections about the site of neuralgic pains are sometimes simply marvellous in the relief they procure. Most of the pain-relieving agents, when applied to the nerves themselves, interrupt the transmission to the sensorium of the painful impression. From these considerations we obtain a useful lesson as to the utility of localised injections for the relief of neuralgia. Dr. Bartholow mentions that he has applied this method with success by the "deep injection of chloroform," and also has used with excellent result the deep injection of chloral, morphia, and atropia.

In neuralgia of the fifth nerve, the injection may be inserted deeply underneath the cheek or lips about the situation of that division of the nerve which is painful. In sciatica the point of the needle should be made to reach the vicinity of the nerve. But he especially calls attention to the good effects of this practice in the cases of that intractable disease *coccydynia*. In this form of severe pain, the needle should be passed down to the coccyx so that the solution may be made to diffuse over the whole surface of the coccyx. He does not meet many cases of this disease, but in two, the brilliant results which followed justify the most sanguine expectations of the utility of the practice. And so in spinal irritation, and in visceral and parietal neuralgia with points of spinal pain and tenderness, these deep injections are of greatest service.

The hypodermic injection of chloral, morphia, and atropia may, he thinks, be used in minor surgical operations.

In recent torticollis and in lumbago it affords lasting relief. He has witnessed astonishing results from the use of chloral and morphia in the true collapse of cholera. The injection hypodermically of the combination of chloral, morphia, and atropia is of great use occasionally in spasmodic asthma, whooping-cough, and laryngismus stridulus. In angina pectoris, hepatic and renal colic, spasm of the sphincter of the bladder, &c., these agents combined produce results to which they are quite inadequate when used separately.

Irish Sanitation by Guardians.

We have in the latest proceedings of the Castlebar Guardians a specimen of the wisdom of placing the execution of sanitary law in the hands of representative obstructives. We learn from a local paper that the Local Government Board had forwarded a letter from Dr. Kisby, to the effect that a man had died of small-pox, having contracted the disease from his sisters, with whom he lived in the same room, and that he (Dr. Kisby), with the assistance of the police, had prevented a "wake." It was only after several hours, however, that a cart and ponies were found to remove the corpse. The doctor therefore suggested the necessity of facilities, including a spring-van, for future emergencies.

A guardian suggested a light van, such as is used for caskets.

As tender for the cart, according to the specification already advertised, was received, but not accepted. The question was postponed for one month.

In the case of twenty-four defaulters under the Compulsory Vaccination Act, reported by Dr. Blackwell, it was resolved to post notices giving a month's time before proceeding.

The question of the hot-air chamber, proposed by Dr. Jordan, was postponed for one month.

We observe that the chairman of the meeting was a *Mr. Tully*. Perhaps this is the reason that the wisecracks of Castlebar thought fit to postpone every attempt at ~~sanitation~~ for another month. This district is that in which the small-pox inoculation and a resulting virulent epidemic of the disease is most prevalent in Ireland, and

yet the persons to whom Parliament was so wise as to provide the public health of the union will neither provide a cart for removal of corpses, enforce vaccination, nor provide for disinfection. Bravo, Representative local Government!

The late Mr. Adams.

At a recent meeting of the Council of the Royal College of Surgeons of Ireland the following resolution was passed, viz.: "That the Council have heard with profound regret of the death of their revered colleague, Robert Adams, and that they desire to place on record their sense of the great loss thereby inflicted on their College. While thus expressing their own feelings upon this melancholy event, they would also wish to convey to his family their sympathy with them upon their sad bereavement."

The Hampstead Hospital Question.

From the decided action taken by the Metropolitan Asylums Board on Saturday, we presume the question is virtually settled, pending the decision of Parliament.

At the meeting, Dr. Brewer, the chairman of the board, presided, and there was a very numerous attendance of the managers present.

Upon the minutes of the previous board being confirmed, a numerous deputation of landowners, house owners, and inhabitants of Hampstead attended before the board to present a memorial, which had been signed by nearly all the principal owners of land and house property in the district. The memorial set forth that these persons desired to record their opinions that, if the Hospital for Infectious and Contagious Diseases is to remain at Hampstead, the present position is as good as any that could be selected. They expressed themselves as strongly opposed to the agitation against the present site, which had been carried on for so long, and in the majority of cases from interested motives, and they hoped that the Asylums Board would carry out their original determination if Hampstead had been finally decided upon.

Thereupon, Sir James Hamilton proposed the following resolution:—

"The managers having inspected the two sites of land in Mill Lane submitted to them by Mr. W. D. Jeremy, adopt the opinion expressed in the report of the General Purposes Committee, bearing date 30th January, viz., that the site No. 1 is wholly unsuitable for the erection thereon of buildings to be used for the several classes of sick for whom the managers are called on to provide. That site No. 2 is not nearly so eligible as the present site of the managers at Hampstead, and would be equally open to the objections raised against the latter site. That a copy of these resolutions be forwarded to Mr. W. D. Jeremy in reply to his communications of the 21st and 28th January, and that a copy thereof be also forwarded to the Local Government Board."

Mr. Sedgwick seconded these resolutions.

A show of hands was then taken, when there appeared for Sir James Hamilton's resolutions 37, against them 2. The two dissentients were Mr. Marshall, the representative for Hampstead, and Mr. Hopkins, Holborn, which district is stated to have contributed more fever patients to the hospital than any other in the metropolis.

Mr. Currie then proposed a resolution, of which he had

given notice, in reference to the motion of an asylum for juvenile imbeciles, to the effect

"That subject to the sanction of the Local Government Board, the committee for the Hampstead Asylum be authorised to negotiate for the purchase of not exceeding 150 acres of the land offered for the purposes of an asylum for juvenile imbeciles at Dartford."

This was seconded, and after slight discussion carried unanimously.

An Improved Poultice.

At a recent meeting of the Académie de Médecine, Paris, M. Le Fort read his report on a substitute for the ordinary linseed-meal poultice invented by M. Lelièvre, an abstract of which appears in the *Chemist and Druggist*. It is prepared by saturating two superimposed layers of wadding with a solution of *Fucus crispus*, or Carrageen lichen, and drying them in a stove after they had been submitted to strong pressure. In this way a sheet of the consistence of cardboard is produced, a portion of which is cut off when wanted, and soaked in hot water for fifteen or twenty minutes; this swells it out and fills its tissue with a mucilaginous fluid. It has been tried in several of the hospitals, to the great satisfaction of both patients and attendants. It can be prepared in large quantities beforehand, and will keep for a long time without undergoing any alteration. MM. Demarquay, Gosselin, and Verneuil pronounce it to be far superior to the linseed poultice; it keeps moist for more than sixteen or eighteen hours; it does not slip, is inodorous, does not readily ferment, nor does it soil the linen or bed of the patient. The new poultice is destined to render great service in hospitals and ambulances, and, above all, on board ship, where it is difficult to keep the linseed in a good state of preservation.

Jaborandi.

THIS Brazilian plant with the savage name is evidently the drug of the day. It arrived in Europe a year ago. The *Chemist and Druggist* says that now all the wholesale houses are sending to Pernambuco for cargoes of it, and two or three of the smartest of them have already secured small stocks. An excellent account of the action of the medicine has also been published by Mr. Martindale, in the *Pharmaceutical Journal*. This gentleman records the effects produced on himself by a dose of sixty grains in the form of infusion. This was taken late at night, and was followed in five minutes by a warmth of the blood, an unusual secretion of saliva, uneasiness in the head, and restlessness, succeeded soon by a violent perspiration. This was continued for more than an hour, when vomiting occurred, and in another hour sleep ensued. Evidently the medicine is possessed of very important properties, and it now becomes a question of considerable interest to ascertain the precise principle of the plant to which these effects are due. Mr. Martindale observed that the infusion did not seem to extract the characteristic pungent taste which the leaves possess; but as he swallowed dregs and all, it is not quite certain whether the medicinally active part of the plant is also that which yields this taste. Several chemists are working at the subject, and this doubt will therefore probably be

soon cleared up, and *jaborandine*, or some such alkaloid, may be looked for before long.

Indian Ipecacuanha.

THE drug markets have hitherto been obliged to look to the Brazils as the almost exclusive source of supply of the above valuable medicinal root. The *Chemist and Druggist* reports that there is now, however, a prospect of shipments being made from India shortly, as Dr. King, Superintendent of the Calcutta Botanic Gardens, states that the propagation of the ipecacuanha plant by root and leaf cuttings has been so successful that there is at present in the gardens a stock of 63,000 living plants, whereas four years ago there were but twelve cuttings, of which seven were afterwards accidentally destroyed.

Registrars' Fees for Sanitary Purposes.

NEARLY all the metropolitan parishes have been compelled to accede to the suggestion of the Registrar-General that they should pay the registrars of births and deaths for the weekly returns supplied to the medical officers of health for sanitary purposes. Those parishes which resisted the Registrar-General's proposal that the registrars should supply the number of births registered each week in their respective districts gratuitously, and be paid £1 per quarter for the first fifty and one penny for each subsequent entry, have been compelled to pay in some instances nearly double to the registrars, as they cannot get their returns from the Registrar-General. Paddington have consented to pay 25s. per quarter for the first fifty, and 2d. for each additional entry. The St. Pancras registrars have agreed to accept £1 for the first fifty deaths, and 2d. for each subsequent entry per quarter. In Marylebone a somewhat similar arrangement has been made, but in some of the parishes as much as 30s. for the first fifty, and 3d. for each subsequent entry is demanded by the district registrars.

Dr. Hardwicke and the Paddington Vestry.

SINCE the appointment of Dr. Hardwicke to the coronership for Central Middlesex, his post as medical officer of health and food analyst for the parish of Paddington has for some time been before the vestry of that parish, who not unnaturally considered it impossible that he could properly discharge those duties as well as those of coroner for the extensive and populous district over which he has been elected to preside. At the last meeting of the vestry a statement was received from Dr. Hardwicke to the effect that, seeing that he was about to prepare his annual report, and therefore desired to complete his inspection of the parish, he proposed to defer the relinquishment of his office in June next. The subject was adjourned till the next sitting of the vestry.

ON Wednesday last, in the board-room of Charing-cross Hospital, Mr. Hancock, F.R.C.S., Consulting Surgeon to the hospital, and a former President of the Royal College of Surgeons of England, was presented with his portrait, the cost of which had been subscribed by the staff, students, and friends of the hospital.

The Coming Medical Bills.

WE learn, upon authority which we believe will be found reliable, that the British Medical Association has matured its Bill, and is only delaying offering it to the House for the purpose of arranging the method of its introduction. The Bill, we believe, is exactly the same as the last emanation of the Association—Direct Representation and Unification of Examination—saving that it proposes to abolish the power of appeal from the General Medical Council to the Privy Council, now enjoyed by licensing bodies. The Association desires, in fact, to perfect the Medical Council according to its own views, and then to make the decision of that body final. As this abolition of the appeal jurisdiction of the Privy Council cannot be expected to be popular with the Privy Council office, or its medical adviser, Mr. Simon, we understand that the Association is making an effort to bring in their Bill through the agency of the Home Department, and if they succeed we shall see it on the table of the House very shortly.

The Enabling Bill of the London College of Surgeons is also, we have reason to believe, ready, and will be moved to its first reading within a week or two, if not sooner. It will probably pass without challenge, and then the Conjoint Scheme for England will be *un fait accompli*. Our readers will recollect that the programme of the conjoint authorities in England (including the three Universities and the two Colleges) has been already promulgated, and it indicates an immediate and sweeping reduction in the lecture curriculum, and a £30 fee for the conjoint diploma. We wonder how long it will take to teach the Dublin lecturers that their "three-course" policy must come to an end? What has come of the convenient prognostics of those advisers of the Dublin College of Surgeons, who last June protested that a conjoint examination for England was all moonshine, and that their College might keep up its scale of lectures and of fees as long as it liked.

The Adulteration Bill.

MR. SCLATER-BOOTH'S Bill has reached our hands at too late a period for us to print for our readers; we cannot, however, allow a week to pass without putting the profession and the public, so far as we can, on their guard against it. Those who read the evidence before the Select Committee, and their report to the House, will have been prepared for a retrograde measure framed for the protection of the traders, and providing little safety either for the stomach or the purse of the consumer. The Committee was decidedly over-manned with manufacturers, and the evidence brought before them was of a very one-sided character, and it is not to be wondered at that the resulting measure deals very tenderly with the money-making adulterator.

The provisions of the Bill are such—we do not hesitate to say—as to make the conviction of a vendor of fraudulent goods almost impossible. Under its clauses it will be necessary, first of all, to prove that the shopkeeper knew of the existence of the adulteration when selling the article. It is needless to say that, if the Bill becomes law, shopkeepers will take good care to know nothing

about it, they will ask no questions, and the manufacturer will not be in haste to give them information, and—even if they should be well informed as to the impurity of the goods—it will obviously be the most difficult task in the world to prove them to be so.

But if the adulteration and the guilty knowledge of it be proved, then the culprit is empowered by the Bill to plead, if a manufacturer—

1. That he did not intend it to be sold in the impure state; or, if a dealer—
2. That the article was of the "nature, substance and quality demanded by the purchaser," or
3. That the impurity was mixed in the article "for the purpose of rendering it portable or of preserving it," or
4. That the ingredient is mixed in it "for the purpose of rendering it palatable or improving its appearance," or
5. That it is "the usage of the trade" to sell the article as adulterated, or
6. That the impure article is patented, or
7. That the adulteration is effected with the knowledge of the Excise, or
8. That the admixture is "unavoidable," or lastly,
9. That the purchaser has been informed by label that "the article is mixed."

We ask, is there any conceivable form of adulteration that will not be covered by one or other of these clauses? Cannot it be pleaded that cocoa which is two-thirds starch is adulterated to make it palatable; that mustard, one half flour and turmeric, is improved in appearance; that Prussian blue is affixed to tea for the same purpose, or to preserve it; that it is the "usage of the trade" to add two-thirds of plaster of Paris to sulphur; that whisky-doctoring is done under the wing of the Custom House; that one-fourth of sand in scammony is "unavoidable."

If this Bill passes it will become obvious that the Legislature of a "nation of shopkeepers" is over-weighted by the shopkeeping interest themselves, and that trade frauds are deliberately protected by Parliament because dishonest money-making cannot be interfered with.

The only honest method of dealing with the matter would be to allow traders to sell anything they liked so long as it was not injurious to health, but to force them with an iron hand to state honestly and without the customary equivocations the true constituents of what they sell.

We shall print an abstract of the Bill and the debate on it in our next.

By telegram we learn that at the fire of a lucifer match factory at Goeteborg, near Stockholm, on Saturday, 44 persons were burned to death and nine others mortally injured.

THE Yorkshire Exhibition of Arts and Manufactures will open on the 6th of May and close at the end of September. The sanitary department is under the supervision of the honorary secretaries, Dr. Goldie, Medical Officer of Health for Leeds, and Mr. J. S. Loe, M.R.C.S.

WE observe that a spectacle mechanist in Dublin, of the name of Sandheim, is making in the columns of the *Irish Times* a great point of his special qualifications, inasmuch as he "has provided a room specially arranged

for the examination of eyes by means of the ophthalmoscope, so that their true state may be ascertained in order that the selection of really appropriate spectacles may result. There is (the *Irish Times* believes) no similar house in Dublin where so great a boon as an ophthalmoscopic room exists."

The *imprimatur* of the *Irish Times* is not, in optical matters, a very high qualification, but for the information of our contemporary we may be allowed to observe that, in the great majority of cases, Mr. Sandheim might nearly as well examine a patient's toe-nails as subject him to an ophthalmoscopic investigation for the purpose of fitting him with spectacles. If the *Irish Times* has taken its inspiration from Mr. Sandheim himself, it is evident that that gentleman, though armed with so high an approval as that of our contemporary, is very little of an expert in focal derangements of the eye.

Literature.

A MANUAL OF HYGIENE, PUBLIC AND PRIVATE. (a)

THE progress of civilisation, the increasing development of arts and manufactures, together with the tendency of populations to condense round industrial centres, and the influence of these circumstances on the health and well-being of a people, demand a continued study of the phenomena of disease, its propagation and prevention.

Disease is not, strictly speaking, natural to man, and was probably unknown in the earliest ages of the world. The death with which our race was originally cursed was not the premature death from disease; nor did the "sorrow" with which woman should bring forth children include the abnormal cases which are daily witnessed in our lying-in hospitals and elsewhere.

That some diseases are the result of the violation of known natural laws has been proved; that similar proof has not been extended to all disease may, we think, be attributed to our want of knowledge. What additional offence did the race commit, or what hygienic principle was violated, that the years of our life should be reduced to less than one-tenth of their original number? That the massing together of large numbers in comparatively small areas—as in our larger cities—is in itself contrary to nature may be probable; but certain it is that the health of such masses cannot be preserved without the aid of sanitary science. Has hygiene heretofore received the amount of attention it deserves? Is not prevention better than cure? Are we much better prepared now, to receive a visitation of the "black death" or cholera than when these epidemics decimated our population? In our cities we know are gurlieus the filth and squalor of which causes us to wonder how, even in the absence of all epidemics, the teeming population manage to exist at all. Dr. Cameron truly remarks with reference to a return of such epidemics as those referred to, "I fear that in some of our towns the virus of the disease would find a genial soil," and in the chapter on vital statistics he observes: "Every death from a preventible disease is an accident, and not a natural and inevitable event. Nor are the maladies termed constitutional necessarily inherent in man's nature; most of them are the result of privation, hardship, intemperance, gluttony, and immorality. Many of them are produced by breathing bad air or drinking foul water."

Dr. Cameron has carefully collected and tabulated much valuable statistical information, possibly already known to

many in the profession, but which will be new to most of his non-professional readers.

In the 20 years ending 1749 the death-rate among children under 5 years of age in London was 745 per 1000; in the 20 years ending 1870 the death-rate was reduced to 298 per 1000. Though this result is due mainly to improved hygienic conditions, it is also considerably affected by the increased medical skill and careful treatment of incidental diseases. It may be remarked, however, that some delicate children which would formerly have succumbed under the treatment which they then received, are now kept alive and reared by refined medical skill, and in their turn will probably become the parents of still more delicate offspring, requiring still greater skill to keep them alive; whether this will result beneficially to succeeding generations is at least questionable. The efforts of the hygienist are rightly directed to the prevention of disease rather than its cure.

Referring to the large amount expended on our army and navy, Dr. Cameron asks, "Are there not other enemies than our fellow-men whose power we should always be prepared to resist?" The best way to prevent war, admittedly, is to be thoroughly well prepared for it—the same principle would be wisely observed in sanitary matters.

Concerning Water supply, much valuable information is given, and the subject is comprehensively treated in a hygienic point of view. The impurities of water, its analysis, and how it acts as a carrier of disease are well explained and illustrated.

As regards quality, Dr. Cameron states: "So far as my observation extends, I am clearly of opinion that the substitution of the pure soft water of the Vartry for the hard water supplied by the canals has produced an improvement in the public health." The fact that adjoining each other on the south side of Dublin are two large townships, one supplied with soft, the other with hard water, presents a favourable opportunity of comparing the relative hygienic merits of the two qualities.

Chapter xi. treats of the Ventilation and Heating of Dwellings. The methods described are worthy of attention, we think, however, that the most complete arrangement for the removal of impure air (though unnoticed by Dr. Cameron) is that in which a special ventilating shaft is provided in each house, having a draught or upward current generated in it by means of any convenient source of heat—a ventilating flue from each principal apartment, opening into the shaft, draws off the vitiated air. The suggestions relative to the lighting of theatres, &c., have been long since anticipated and carried into practice.

We do not agree with Dr. Cameron that "open fireplaces are ventilators of the most effective kind;" that they abstract a large quantity of air from an apartment is quite true, but it is from the lower, colder, and purer stratum the air is removed, which is not an advantage, while the upper and impure air is left comparatively unaffected.

When it is considered that only 17 per cent. of the heat generated in open fireplaces is available for warming an ordinary room, we think it is reasonable to expect that some improvement on the present open fireplace might be introduced.

The Pollution of the atmosphere by Manufactures is succinctly described, and an account is given of some of the effects as personally observed by the author last year in Lancashire.

The chapters on Meteorology, &c., Contagion, Vaccination, Disinfectants, Construction of Hospitals, and School hygiene, do not appear to add much to our previous knowledge on these subjects; they are, however, well written and contain a large amount of condensed information, carefully, and we can say from experience, laboriously collected from known authorities.

Dr. Cameron's remarks on Sewers and Sewage are sound and practical, and might be advantageously studied by every intelligent member of the community. A sort of reckless indifference is generally prevalent about these

(a) "A Manual of Hygiene, Public and Private, and Compendium of Sanitary Laws, &c." By Charles A. Cameron, Ph.D., M.D., &c. London: Baillière, Tindall, and Cox. Dublin: Hodges, Foster, and Co. Price 10s. 6d.

matters. So long as the sewage matter is got out of the way and into the main sewer people seem satisfied; but we venture to say, that in nine-tenths of our houses the sewage arrangements would be found defective—for instance, it is a common practice for the overflow pipe of a cistern to communicate openly with the sewer; the syphon trap so generally used ceases to be effective when deprived of water, and this, in many instances, occurs in summer when the water is evaporated.

The chapters on Exercise, Bathing, and Clothing, on Unsound Food, and the Adulteration of Food and Drink, we recommend to the perusal of all.

The work concludes with a comprehensive collection of the sanitary statutes applicable to Ireland.

There are few who are so eminently qualified by their position as Dr. Cameron to write on sanitary science, and we recommend his work to the profession as a valuable, and we have every reason to believe, a reliable compendium on this subject; to sanitary officers, as a safe and practical guide in the discharge of their duties; and to all intelligent heads of families as a director which will enable them to add to the comforts and diminish the evils which surround them.

Correspondence.

TREATMENT OF THE DISEASE CALLED "FEVER."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having in your columns of the 16th Dec. given my views of this disease, and added something relative to its treatment, I now propose to enter a little more particularly into the latter. I have said, and I think scientifically proved, that this disease is similar in all climes, as a crotchety symptom will not alter its condition, that the symptoms are similar, and that the apparent difference, if any, depends upon the activity of the poison. I have, I also think, scientifically proved the tendency of arterial action to the mucous coat of the alimentary canal. From the most leucoplegmatic, starved subject, to the most phlegmatic and robust, the arterial action is the same, though not so visible either during life or after death in the former, as you could not expect any marked signs of high inflammatory action from the impoverished state of the blood, the inability of the heart to drive it, or the mild action of the poison, but, it is not the less fatal; hence the scientific treatment will be the same in all cases. In tropical climates, where the skin is intensely hot, the pulse high, and the thermometer the same almost day and night, I would clear the bowels by castor-oil, because time is valuable, indeed, I think it would be most prudent in all cases, as you can graduate the doseless mixture, and it would be more satisfactory. If the nitrate of potash will clear the blood of all foreign colouring matter, whether the result of decomposition or otherwise, I think in its doing so it should destroy or remove the cause. Mercury equalises the circulation, clears the blood, and removes the disease; therefore I think it must possess the same destructive quality: these scientific facts, I think, have been satisfactorily proven; it therefore follows that we can use both at the same time, if necessary; the citrate or tartrate of soda will not purify the blood, though they may slightly allay thirst, they may relieve momentary gastric irritability, but they do not relieve inflammatory action. I have gone through, as I formerly said, the Pharmacopœia, from Alpha to Omega, and, with the exception of mercury and the nitrate of potash, I have not been able to lay my finger upon one of any scientific value in this malady. The nervous system should be quieted by opium, morphine, or belladonna. Quinine has been given as an antidote, or preventive, but, unless in intermittent forms, we should require more satisfactory proof in this malady; sponging the body frequently with cold water containing two or three ounces of the nitrate of potash to the gallon would be grateful, and materially assist in allaying thirst independent of its properties being absorbed; in applying cold to the surface we should be cautious so as not to procure chills or rigors, as they might be the cause of much unpleasantness hereafter. It should be remarked in the cure of this malady that, as

the urine becomes clearer and less disagreeable, the patient improves and gets better. Food should never be forced. What state is the stomach in? What kind, if any, of gastric juice is secreted?—is it strong enough to digest food? When the stomach attains strength it will ask for food; at the same time, thin arrowroot or corn flour, with wine, when requisite, is not objected to in small quantities. When the stomach is engaged in repelling a very active intruder it has no disposition for food. When you find that medicine has been useless, whether the case has been treated as fever or gastro-enteritis, and symptoms of a typhoid character present themselves—and they are proofs of great constitutional debility—the struggle has commenced between the strength of the constitution and the disorganised arterial blood, as the virus of the poison is dead, and the symptoms of active inflammatory action have disappeared. Science now points out that the system must be upheld by food and stimulants, wine, brandy, or whisky, pure or diluted, according to the state of the case; those symptoms require all the attention of the medical attendant, as a very short neglect will turn the scale; and the nurse becomes a most important personage, as any neglect on her part may prove fatal. Nature will sometimes do wonders when properly assisted and scientifically supported. Nature has often put physic to the blush, though very seldom paraded to public view; but this is a disease which does not stand upon much ceremony. I have seen about twelve ounces of brandy given in black vomit and restore life, and I have known a wineglassful of whisky do the same when all hope had been given up; it is, therefore, at that period when typhoid symptoms commence and medicine ceases to benefit, that the stimulating and supporting system should commence. Ask the plain, straightforward question in this disease—What are the arteries, veins, nerves, and lymphatics doing? Man is composed of these, and of nothing else, except blood. The arteries and veins are circulating disorganised blood; the nerves are telling us what is going on; and the lymphatics are secreting and absorbing an unhealthy fluid. Arteries, what are you doing? We are carrying compulsorily this terribly disorganised blood. These are what I call scientific questions and answers and facts, which may perhaps lead some scientific men to consider this malady more seriously. The very urine itself should show you what a terrible state the blood must be in.

I am, Sir,

Yours faithfully,

ALEX. LANE, M.D. R.N.

Douglas, Isle of Man.

January 11, 1875.

P.S.—Before a man can "pooh pooh" any proposition or doctrine established upon scientific principles, he must be prepared to refute the same upon similar principles, else keep silent. If I have advanced anything scientifically wrong, for physic is a science just as much as anything else, and should be contested upon those principles, as, for every scientific why there is a scientific wherefore—let it be refuted scientifically, the laws of animal economy are scientific. There is science in the cutting off of a limb, and there is science in administering a dose of medicine. Why do you give it? What is its action? What results do you expect? If I can be proved scientifically wrong, it will be for the advancement of physical science and the benefit of the human race.—A. LANE.

Medical News.

Royal College of Physicians of London.—Pass List, February 20, 1875.—Admitted Licentiates:—

John William Davies, Ebbw Vale, Monmouthshire.

William Adams Frost, 47 Ladbrooke Square, W.

William Hardman, Blackpool.

Alfred de Courcy Lyons, 15 Vicarage Gardens, W.

Henry William Mason, 19 Granville Square, W.C.

Charles Joseph Stocker, Stratford Green, E.

Robert Thomas Thomas, 34 Great Percy Street, W.C.

The following Candidate, having passed in Medicine and Midwifery, will receive the College Licence on obtaining a qualification in Surgery recognised by this College:—

David Edwards, University Hospital, W.C.

NOTICES TO CORRESPONDENTS.

NOTICE TO SUBSCRIBERS.—The Publishers will be glad to receive the subscriptions for the past year, 1874—£1 2s. 6d. Subscriptions in advance for 1875, at the reduced tariff of 21s. per annum, post free, are now due, and also will be thankfully received by the Publishers in London, Dublin, and Edinburgh.

SCARCE NUMBERS FOR 1874.—The Publisher will be glad to purchase clean copies of May 30, June 3, November 18, or to exchange any other numbers for them.

PROPOSED REFORM IN MEDICAL PRACTICE IN DUBLIN.

We are favoured with the following interesting and appropriate suggestions by a correspondent:—

On looking over the names of our Dublin medical men, it has occurred to me that much convenience would result from each devoting himself to that branch of his profession indicated by his name. Thus I would place the lunatic asylums under the charge of Dr. Madden, the more violent cases being attended to by Dr. More Madden. I think that Drs. Boyes and Birch might fairly be deputed to look after the weaknesses of young persons; while Dr. Luther would be at home in charges of the Adelaide Hospital. The Lying-in Hospitals fall naturally to Drs. Bredin and Kidd; while hysterical affections should be treated by Drs. Cryan, Smyly, and Lafan. Diseases of the bladder might be left to Dr. Stoney; while for baldness I do not know any more suitable advisers than Drs. Hare and Head. All matters relating to fees should be referred to Dr. Price; while attendance should be regulated by Dr. Daly. For lameness I would consult Dr. Walker and Foot; for shot wounds, Dr. Gunn; but for operative surgery, undoubtedly Surgeons Steele, Butcher, and Gore would be selected. For skin diseases, I would call in Dr. Peck; while questions of food might be left to Dr. Fry, Boyle, Cooke, &c. and Porter.

For cases of physicians, I would name Drs. King and Duke; and I would place the faring men under the charge of Dr. Cruise. For colour-blindness, Drs. Brown, White, Gray, Green, and Dunne might be useful; while for "gatherings" I would certainly consult Dr. Cameron ("The wild and high the Camerons' gathering rose"). Questions as to abnormal size or development might be referred to Drs. Long, Short, Little, and Bigger; and matters relating to medical jurisprudence to Drs. Wise, Law, Fox, and Wright.

Hypochondriacs I would place under the care of Drs. Blythe, Bright, and Hope; and I would place the following over institutions connected with the working-classes: Dr. Butcher, Baker, Taylor, Smith, Butler, Carpenter, Sawyer, Cartor, Fisher, Glover, Mason, and Stoker. As Treasurers of the Medical Benevolent Fund, the names of Dr. Purser and Banks at once present themselves; and it might be a nice compliment to our Lancashire neighbours if we were to send Dr. Wilde and Savage to them for a short time. All cases of debility would be attended by Dr. Power, and monastic and other similar institutions would of course be left to Dr. Monks.

Finally, I suggest that after all the above long list of eminent men, many of them world-famous, have done with us, it might be well for our friends to call in Dr. Sexton.

14 Royal Terrace, E. Kingstown,

H. E.

PROFESSIONAL ADVERTISING.—A correspondent has forwarded us a copy of the last *Lincoln Gazette*, in which is inserted an advertisement of a local practitioner, which appears to us scarcely professional. Of course, there may be some special reason unknown to us at a distance which has prompted its insertion; but if it is intended as a continuous announcement, we are decidedly of opinion that the gentleman concerned has been badly advised, and would, we are sure, be glad to rectify an error of judgment when his attention is drawn thereto.

MR. J. T. B.—We have not space for the letter, the subject not being of sufficient interest to our readers.

DR. CAREY, Taunton, will please receive our best thanks.

PSYCHOLOGIST.—The work, "The Building of a Brain," to which you refer, has not been received by us for review, nor have we seen any announcement of its publication. We devote a column monthly to an index of new works in medicine and the allied sciences, to which we would refer you for any future similar inquiry.

KING'S COLLEGE HOSPITAL.—We are requested to state that the annual court of the corporation of this Hospital will be held in the Board Room to-morrow, Thursday, at 4 p.m.

DR. GREENHOW will lecture on "Addison's Disease" at the Royal College of Physicians, London, on Wednesday next, at 5 o'clock. Members of the profession admitted on production of their cards.

COMMUNICATIONS, Enclosures, &c., have been received from—Dr. Carey, Taunton. Dr. Balthazar Foster, Birmingham. Rev. Dr. Haughton, Trinity College. The Director-General of the Indian Medical Department. Mr. Dunne, Clana. Mr. Collins, Glasgow. Dr. George Johnston, Dublin. Dr. Fixott, St. Heliers, Jersey. Mr. G. Gibson, Broughton, in-Furness. Mr. Blacker, Midsomer-Norton. Mr. Fowler, Greenwich. Mr. E. Stevens, Islington. Dr. Gaillard, Louisville. The Director-General of the Navy Medical Department. Dr. S. Bryant, Brighthelm. Mr. Hanslip Sers, Epperstone. The Director-General of the Army Medical Department. Mr. James Hogg, London. Dr. Bayes, London. Mr. Short, London. Dr. Birchall, Maclesfield. Dr. Greene, Peckham. Mr. Hyalop, Stretton. Dr. Dickinson, London. Mr. Gould, Southwark. Mr. Holden, Liverpool. Mr. Whitall, Statistical Society. Mr. J. T. Baker, Bethnal Green. Dr. Handal Griffiths, Dublin. Mr. Royle, London. Dr. Waring Curran, Mansfield. Dr. Duffield, Kensington. Dr. Lombe Athill, Dublin. The Registrar, Royal College of Physicians of London. Dr. Lethby, London. Dr. Donovan, Cork. Dr. Corry, Belfast. Dr. Bell Taylor, Nottingham. Mr. Eakell, Dublin. Mr. F. Agar, Ponder's End. Dr. Lloyd Davies, Abergella. Dr. Dobell, London, &c.

MEETINGS OF THE LONDON SOCIETIES.

WEDNESDAY, Feb. 24th.—Royal College of Surgeons, 4 p.m. Prof. W. K. Parker, "On the Structure and Development of the Skull." **ROYAL COLLEGE OF PHYSICIANS.**—5 p.m. Dr. R. J. Lee, "On Puerperal Fever."

HUNTERIAN SOCIETY.—7½ p.m. Council Meeting. 8 p.m. Dr. Sedgwick Saunders will give his Presidential Address. Mr. R. Clement Lucas will exhibit a Case of Excision of the Ankle-joint. Mr. Davies Colley, "On Two Cases of Diffuse Palmar Ganglion treated Antiseptically."

FRIDAY, Feb. 26th.—Royal College of Surgeons.—4 p.m. Prof. W. K. Parker, "On the Structure and Development of the Skull."

ROYAL COLLEGE OF PHYSICIANS.—5 p.m. Dr. R. J. Lee, "On Puerperal Fever."

QUERKETT MICROSCOPICAL CLUB.—8 p.m. Mr. B. T. Lowne, "On the Histology of the Eye."

CLINICAL SOCIETY.—8½ p.m. Adjourned Discussion on Dr. Vivian Moore's Case of "Paralysis of Serratus Magnus," and Dr. Southey's Case of "Lepra Anæsthetica." Mr. Pugin Thornton, "On a Case of exceeding Infrequency of the Pulse." Mr. John W. Teale, "On a Case of a very remarkable Elevation of Temperature (to 120°) after Injury to the Spine." Dr. Whigham, "On Fatal Pleuro-pneumonia in an Opium-eater."

MONDAY, March 1st.—Medical Society, 7 p.m. General Meeting for the Election of Officers and Council.

TUESDAY, March 2nd.—Pathological Society, 8 p.m. Ordinary. **ROYAL INSTITUTION.**—9 p.m. Mr. A. H. Garrod, "On Animal Locomotion."

VACANCIES.

St. Bartholomew's Hospital. Two Casualty Physicians. Honorary. Applications to be left at the Clerk's Office.

London Fever Hospital. Resident Medical Officer. Salary, £200 per annum, with residence, &c. Applications to be addressed to the Secretary, at the Hospital.

Queen's Hospital, Birmingham. House Surgeon. Salary, £50, with board and residence. Apply to the Secretary.

Coventry Hospital. House Surgeon. Salary, £100, with board and residence. Applications to the Secretary.

Chorley Union. Medical Officer of Health. Salary, £150 per annum. Full particulars of the Secretary.

Chelsea Dispensary. Surgeon. Honorary.

Dorset County Hospital. House Surgeon and Secretary. Salary, £20, with board and residence. Applications, under cover, to the Chairman.

Clinical Hospital, Manchester. House Surgeon. Salary, £80, with board and residence. Address the Chairman of the Medical Board.

West Riding Asylum. Clinical Assistant. Board, residence, and instruction in return for services. Address Dr. Crichton Browne, Wakefield.

Landport Union, Somerset. Medical Officer for the Babcoay District. Salary, £27, with fees extra. Apply to the Clerk of the Union.

APPOINTMENTS.

BALLEWEN, J. M'N., M.D., L.F.P. & S. Glas. Medical Officer of Health for the Upper Sedgley Urban Sanitary District.

BARBER, S., M.D., L.R.C.P. Physician to the Asylum for the Blind, Brighton.

CARRÉ, F., F.R.C.S.I., L.K.Q.C.P.I. Consulting and Visiting Physician to the Donegal District Lunatic Asylum, Medical Officer to the Fever Hospital, and Medical Attendant to the Royal Irish Constabulary, Letterkenny.

DRAPER, W., M.B.C.S.E., L.M., a Surgeon to the York Dispensary.

DUDLEY, F. J. R., M.R.C.S.E., Medical Officer for No. 3 District of the Ashton-under-Lyne Union.

FRENCH, J. G., M.R.C.S.E., a Medical Officer to the Wells, Somersetshire, Cottage Hospital.

FRYER, C., L.K.Q.C.P.I., L.M., Medical Officer for the Sherburn District of the Scarborough Union.

HARRIS, Dr. S. J., Assistant Surgeon to the London Provident Surgical Appliance Society.

HEASTIE, Mr., of Wolverhampton, Assistant to the House Surgeon and Dispenser, Staffordshire General Infirmary.

KERR, A. T. H., L.R.C.S.I., Resident Assistant Surgeon to the Amalgamated Friendly Societies' Provident Dispensary, Preston.

LIVETT, H. W., L.R.C.P.Ed., M.R.C.S.E., a Medical Officer to the Wells, Somersetshire, Cottage Hospital.

LYON, J. G., M.A., M.D., L.R.C.S.Ed., Dispensary Surgeon to the Western Infirmary, Glasgow.

PURNELL, R., M.D., M.R.C.S.E., a Medical Officer to the Wells, Somersetshire, Cottage Hospital.

WATTS, A. N., L.R.C.P.Ed., L.M., M.R.C.S.E., Medical Officer for the Sharnbrook District of the Bedford Union.

Marriage.

WILKINSON—ALLEN.—On the 16th inst., at St. Mary's, Lambeth, London, Hubert Henry Birkett Wilkinson, L.R.C.P., L.R.C.S., L.M., of Botherham, Yorkshire, to Mary Agnes Cecilia, only daughter of the late Captain James Allen, R.N., of Jersey.

Deaths.

DR. NEORI.—On the 8th Feb., Athenodore De Nègri, M.B., of Belisle Road, St. John's Wood, aged 35.

DRAKE.—On the 14th Feb., Thomas Drake, M.R.C.S.E., of Richmond, Surrey, aged 69.

MARTINDALE.—On the 13th Feb., Wm. Martindale, M.D., of Holland Road, Kensington.

MERRYWEATHER.—On the 11th Feb., at Colville Road, Baywater (suddenly, from a spasm of the heart), Philip Edward Collins Merryweather, M.R.C.S.E., aged 49.

NICOLSON.—On the 9th Feb., at Forest Hill, Charles Patrick Nicolson, M.A., M.B., F.S.C., aged 51.

NORTON.—On the 16th Feb., Edward Norton, M.R.C.S.E., of Upper Baker Street, aged 65.

WHIDBORNE.—On the 13th Feb., G. F. Whidborne, L.R.C.P.Ed., of Ketter, aged 66.

A Course of Lectures

ON THE

NATURE AND TREATMENT OF DEFORMITIES OF THE HUMAN BODY,

DELIVERED IN THE MEATH HOSPITAL, DUBLIN, BY

LAMBERT H. ORMSBY,

Surgeon to the Hospital, and Demonstrator in the School of Surgery Royal College of Surgeons in Ireland.

LECTURE IX. (continued).

THE DEFORMITIES OF THE UPPER EXTREMITY.

DEFORMITIES OF THE FORE-ARM.

These may arise from derangement of the osseous and muscular system in this situation.

Ossous.—The ulna and radius in a constitution that suffers from rickets are found frequently considerably bent or bowed; in fact, the bending owing to rickets is generally seen in the first instance in these bones before any other bone in the body becomes bent from the disease, very likely because children crawl about on their hands and knees before they can walk, and the superincumbent weight of the upper half of the body is more or less supported by these bones. In very early infancy, when these bones are bowed, they can be easily straightened when moderate force is applied. I have frequently straightened bones in this manner; they do not break, but are so flexible that they will bend like a green stick, and a splint being applied to prevent the bones returning to their abnormal position, and proper constitutional remedies administered to correct the deficiency of the lime salts required for rendering the bones more stable.

I had a case a short time ago under my care, an infant three months old, that was brought to me by a lady, who stated that the child when born was noticed to have

something irregular about its hands and fore-arms, and the bones in both fore-arms were so twisted as to resemble what is termed a *club-hand*, that is, the hand and wrist appeared as if it were twisted round twice. A curious fact about the child was that it had but four fingers on each hand, the thumb in each being absent. In that case I forcibly twisted the hands in the opposite direction until I got them straight, and then applied a straight light metallic splint, and the last time I saw the case it was doing remarkably well. Debility of the muscles in the fore-arm frequently arises from the various forms of paralysis, and also from the introduction of some poisonous mineral, such as the deformity that is called *lead palsy*. For such cases a variety of mechanical instruments have been suggested and used very largely by M. Duchenne, such as Figs. 25, 26. Galvanism is also most useful, and various gymnastic exercises enforced for the purpose of coaxing the paralysed flexors and extensors into healthy action; the muscles are frequently found flaccid, small, and ill-developed, owing to want of use.

DEFORMITIES OF THE WRIST AND FINGERS.

These may be considered under three heads—viz., Accident, Disease, and Debility.

Before mentioning in detail the various deformities under the above heads, I should mention that congenital dislocation of the bones constituting the wrist-joint is occasionally met with. Mr. Adams, of Dublin, records thirteen cases, and Cruveilhier has also seen such cases. I saw such a case a short time ago in a baby, where there was dislocation of both bones backwards, producing great deformity, giving the hand a very clubbed and abnormal-looking appearance.

From Accident.—Comprise a great number of deformities affecting the utility of the wrist-joint, hand, and fingers in a variety of ways. I have seen much deformity produced by the healing of wounds caused by gashes of chisels, cutting some of the flexor tendons, passing the hand through a pane of glass, hand caught between two rollers, and other machinery accidents, the bursting of guns, and other explosive materials, and in some cases frightful deformity is produced by burns and scalds, contraction of

the various tendons passing underneath the anterior and posterior annular ligaments, in such cases division by

FIG. 25.

Mechanical Appliance for remedying Paralysis of the Extensor Muscles of the Hand.

tenotomy sometimes gives great relief. Much can be done and much deformity prevented if care is taken to keep the hand in a useful position by splints and appliances during the healing of such injuries implicating the hand and wrist; and, again, gentle passive motion and manipulation should be frequently set up at stated intervals to prevent the various carpal and phalangeal articulations from becoming stiff and ankylosed. Contraction of one finger or more may occur, so much so that it becomes so contracted as to oppose all efforts to extend it, and for the relief of which we have many ingenious appliances at our disposal—appliances made with india-rubber bands, to simulate the action of the muscles. In some cases patients frequently ask to have the contraction of the fingers divided with a tenotome, and I invariably refuse to do so, unless I see a reasonable hope of improving the case, because if you divide the flexor contraction the finger may become straight, but it will then remain constantly extended, which is more noticeable than if it were partly bent. Constant and gentle traction, assisted by some simple mechanical instrument, I find in many cases to succeed in improving such a deformity.

From Disease.—The wrist-joint is a most common situation for the various forms of inflammatory affections ending in derangement of the articulation, and these inflammatory affections may be either specific, such as scrofulous, syphilitic, or rheumatic; or non-specific, such as simple acute arthritis; all, however, very often affect this articulation, leaving more or less impairment after subsidence of the inflammation. These affections, as a matter of course, are treated in precisely the same way as other inflammations, and any operative measures should be well considered before putting them into effect. Much can be done through constitutional remedies, by strong and antidotal tonics. Chronic rheumatic arthritis frequently affects the joints of the wrist and fingers, and distorts the hand and fingers considerably. In some cases chalk stones are

FIG. 26.

Mechanical Appliance for remedying Paralysis of Flexor Muscles of Fore-arm and Hand.

deposited outside each articulation, producing excessive pain, and destroying the joint completely. Neglected whitlow very frequently ends in much deformity, contraction of fingers, impairment and total destruction of joints; and in a working man I have frequently had to remove entirely the contracted fingers as it was in the way, and prevented the complete action of the other fingers. Enchondromatous tumours frequently affect the metacarpal and phalangeal bones, and produce ugly tumours of different sizes; these are benign cartilaginous growths, and can be removed by operation with the greatest ease. Any form of disease affecting any of the carpal, metacarpal, or phalangeal joints is frequently attended with great deformity in the way of swelling and chronic thickening, and hypertrophy, resulting in more or less impairment. *Synovial tumours* are frequently seen in the region of the wrist, and are quite independent of the radio-carpal articulation; they are separate and independant cysts, or enlargements of the various bursæ that are placed round the wrist-joint, placed and attached to the tendons. The synovial cysts called ganglions are very often seen on the back of the wrist and carpus. These small tumours vary in size from a hazel-nut to a pigeon's egg, are, as a general rule, unaccompanied by much pain, are slow in their growth, and contain a clear white of egg kind of sticky tenacious fluid. When talking of ganglions about the ankle-joint, I enumerated all the treatments recommended. There is also a morbid condition of the synovial bursæ of the flexor ten-

dons in front of the wrist-joint. This enlargement sometimes attains a great size, and begins underneath the anterior annular ligament; it goes on increasing, and the fluid simulates synovia as close as possible; this cyst frequently contains a great number of small little pippin-shaped bodies, some indeed the size of wheat or rice, and likened by some to melon-seeds, but are subject to much variety in shape, size, and colour. There is much difference of opinion as regards their origin: Sir Benjamin Brodie believed them to be caused by coagulated lymph which

FIG. 27.

Mechanical Appliance for remedying Muscular Cramps in Fore-arm, Wrist, and Fingers.

was effused in the early inflammatory stages of the disease. The wrist and hand are often liable to be affected with malignant tumours, and, as I mentioned before, by scrofulous and syphilitic derangement of the bones, which may commence like osteitis. After inflammatory action has continued for a lengthened period the hand becomes greatly deformed, so much so in some advanced cases that the outline and contour becomes completely destroyed, and the fingers are all matted and webbed together in one large unhealthy-looking tumour with numerous sinuses distributed over its surface, leading into diseased bone.

VARIOUS CONTRACTIONS OF THE FINGERS.

Contraction of the palmar fascia, owing to contraction of the palmaris longus muscle, producing the various kinds of cranips which are common to the different callings of those who are in the habit of placing their fingers and hand in any peculiar position, such as the *letter stamper's cramp*, *writer's cramp*, and various other deformities common to any special calling, the little finger is found first to become contracted, then the ring and middle finger. These are difficult cases to treat, as they are generally seen in those who have been following out the peculiar trade for a considerable period, and, although with some force the finger can be nearly straightened, it is always inclined to relapse when appliances and force are removed. Again, the contractions may be divided subcutaneously by tenotomy, and is often of use. Appliances such as Fig. 27 may be also applied.

WEBBING OF THE FINGERS.

Webbing of the fingers is a deformity we sometimes

meet with as the result and consequence of an accident, or traumatic injury, the healing in of a wound or severe burn of the fingers and hand. This latter is very frequently followed by union, and considerable webbing of the fingers takes place if very great care is not taken during the healing process. To prevent union of the lateral aspect of the digits, lint, or some substance must be kept constantly interposed between to prevent such a deformity taking place. It may also occur as a congenital affection.

The treatment for such cases varies according to the extent of the union. 1. It may be divided with the knife, and allowed to granulate and heal up, having some substance constantly interposed. 2. Caustics have been used frequently for such a purpose. 3. Running a seton between the web and allowing it to ulcerate its way out. 4. Running a piece of metallic substance topped with a screw through the centre of the web, and so keeping it applied by fastening a knob on the end of the screw, and allowing this web to be broken down bit by bit. This web is constantly inclined to re-unite, owing to the close apposition of the parts.

Many other deformities and changes in the shape of the hand are seen, the effects of various diseases, such as chronic rheumatic arthritis, gouty deposit, and other forms of spasmodic contraction, as well as dislocations and fractures implicating the joints in this situation. The treatment in all depends, as a matter of course, on the exciting cause and circumstances of the case. Deformities of the wrist, hands, and fingers, arising from debility, depend on the different forms of paralysis that affect the muscular system here, as in other parts of the body; all require a certain course of constitutional remedies, as well as active local applications.

CONGENITAL MALFORMATIONS OF THE HAND AND FINGERS.

I mentioned we frequently met congenital dislocation at the radio-carpal articulation, and we find in considering the same subject that children are frequently born with one or two fingers more than the natural number. I have met with six fingers on a hand, and we also find a deficient number. I had a case, before cited, of a baby who had but four fingers on either hand, the thumbs being completely absent, not even a rudiment of such an appearance. When the digits are six or seven in number the digits in excess are always unnaturally placed, and seem to be growing from either side of the fingers; these fleshy protuberances sometimes have not any bones passing up their centre; in others rudimentary bones are present. Treatment for such depends on the circumstances of the case: mostly, however, nothing is done, but leave them alone, except in cases where these morbid growths are a great eyesore, and their position is most inconvenient; then operative measures can be resorted to. Only the other day I removed a supernumerary thumb from a baby aged six weeks. This excessive thumb grew from the base of the second phalanx, and it had all the appearance of the natural thumb, having when dissected a rudimentary bone running up its centre; the fingers and thumb on the other hand were perfectly natural. There was no history of injury, maternal impression, or otherwise, during pregnancy.

ON THE ANTECEDENTS AND TREATMENT OF TERTIARY SYPHILIS. (a)

By C. R. DRYSDALE, M.D., M.R.C.P. Lond., F.R.C.S.E., Senior Physician to the Metropolitan Free Hospital.

MR. PRESIDENT,—I shall always consider it as one of the greatest honours I have had bestowed on me that I have had the privilege of reading a paper on syphilis under your indulgent auspices. It is no small thing to treat

(a) A paper read at the Medical Society of London on the 15th February, 1875, Mr. Victor de Meric, President of the Society, in the chair.

such a subject in the presence of such an eminent pupil and life-long friend of the greatest writer on syphilis of this century, and I am fully aware of my deficiencies in entering on this essay.

Before entering upon the two points I have laid before me for consideration, as to the etiology and treatment of tertiary syphilis, I think it will perhaps be as well for me to give, in one or two paragraphs, the outline of my present creed with respect to the course of the disease before it arrives at the tertiary stage.

From all that I have seen and from all that I have read I am more and more convinced that, when contracted by a previously healthy person, either from contagion from the primary sore or from secondary lesions, the invariable primary appearance of syphilis is an ulcer, which ulcer does not appear until some little time has elapsed after the virus has entered the body. This *time of incubation* may be only a few days, or it may be many weeks in duration, but it *always* exists; and this is one of the points in which syphilis resembles measles, scarlet fever, small-pox, and vaccinia. As to the soft sore, on the other hand, it has no incubation period, and has, in my view, no clear relation at all to the redoubtable virus of syphilis. I confess to belong entirely to the party of the *Dualists*: and I know of no very serious difficulty in the question of the initial lesion of syphilis which cannot, in the vast majority of cases, be solved in a satisfactory enough manner by aid of this theory, which is the result of the labours of Bassereau and the Parisian school of the Hôpital du Midi.

Syphilis, then, like variola, has an incubation period, after which there appears at the point inoculated a slight, and frequently insignificant, ulcer, seated on a hard or parchment-like base, whilst the neighbouring lymphatic glands become hard, and very rarely suppurate.

I further believe, convinced by the experience of Mr. Jonathan Hutchinson, Drs. Ricord, Fournier, Acton, and De Meric, &c., that when mercury is given on the very appearance of the initial lesion of syphilis, which is *usually* easy enough to diagnose (although this is by no means always true), the disease seems to be sometimes cut short, and nothing more is seen of it perhaps in any form—at any rate, the eruptive stage is absent; so that, in several cases of this description where I have lately been consulted, I have given small doses of mercury or of the green iodide of mercury in daily doses for some months to prevent the appearance of the exanthem. As a rule, however, I think it is comparatively rare for practitioners to be consulted for the primary lesion of syphilis until some other symptoms have arisen, such as roseola, sore-throat, or other secondary symptoms. Syphilis, in its secondary stage, has again many points of analogy with the exanthemata. Thus fever occasionally, though, it must be confessed, rather rarely, runs high. In several cases the thermometer shows a temperature of 102° F., or even higher, at the commencement of the eruptive period. I have seen some notable instances of this high temperature in ladies who have acquired syphilis from their husbands, for delicate women like these sometimes suffer terribly from secondary syphilis, far more, as a rule, than men do.

As to the treatment of the secondary stage, I for many years treated all my patients with large doses of iodide of potassium, and must observe that I found many of these cases extremely benefited by this remedy, a statement which has often been called in question, since it is a pretty generally received opinion that iodide of potassium, although confessedly among those I agree with an excellent remedy in the tertiary stage, is not suited to the secondary or eruptive period of syphilis in any case. I think this mistake has arisen from there having been so few persons sceptical enough to ascertain for themselves how secondary syphilis behaves when untreated by mercury.

The formidable revolt against the use of mercury in all diseases, headed in this country by Dr. Hughes Bennett and Dr. Habershon, during the last twenty years, and warmly espoused by Dr. Diday, of Lyons, in certain cases of true syphilis, joined to the experiments of the school of

Christiania, Paris, and, in a few instances, in England, has had its uses in converting the blind or blunderbuss use of mercury in all kinds of unsuitable cases into an arm of precision. Even Mr. Jonathan Hutchinson and Mr. James Lane were, it seems to me, to a certain extent influenced by and indebted to that sceptical movement for the present precision of their teachings with respect to the treatment of the disease, since Mr. Hutchinson mentioned to the Admiralty Commission in 1865 that he had for some length of time treated all cases of indurated sores he had met with at the Metropolitan Free Hospital without any mercury, thus obtaining a basis of comparison on which to place his actual definite views as to the autidotal properties of mercury in this stage enunciated by him last year in the Hunterian Society of London.

It is natural that, as I am making a confession of my recent return to a faith in mercury, I should endeavour to justify myself for my long departure from that prevalent faith, and I cannot do so better than by quoting the words of Mr. James Lane (*British Medical Journal*, Dec. 12th, 1874). Speaking therein about the mercurial treatment of syphilis, he there says: "Nevertheless, I have great doubts whether, in consequence of its flagrant abuses of former times, it has not, on the whole, done infinitely more harm than good: whether, in the treatment of syphilis, it has not been a curse, rather than a blessing, to the human race. I believe that even now we are only beginning to confine its administration within its proper limits; and even now the tendency is in many quarters in the direction of non-mercurial treatment. We are greatly indebted, in my opinion (Mr. James Lane goes on to say), to the anti-mercurialists, and especially to the army surgeons in the early part of this century, amongst whom the name of Mr. Rose should stand conspicuous, for demonstrating the fact that syphilis does not necessarily require mercury for its cure, but has, like most other diseases, a natural tendency towards recovery; that the old rule of action—more syphilis, more mercury—is a mischievous delusion, arising out of the idea that without it syphilis must necessarily go on from bad to worse." No better plea in favour of scepticism with regard to the mercurial treatment of syphilis could be adduced.

Without going into details, I may say that I feel now so convinced by the arguments of Fournier and others that the proper treatment of the secondary period of syphilis, including iritis, mucous tubercles, angina, alopecia, and psoriasis, is mercury, that I am now giving small doses of grey-powder or pills of the green iodide for a prolonged period in this phase of the disease, which lasts often some eighteen months to two years. It appears to me that very small doses (for I still retain a vivid recollection of the evils caused by over-doses of mercury, and which are alluded to by Sir James Paget in his evidence before the Admiralty Commission), of two or three grains of mercury and chalk daily, or one grain of the green iodide of mercury in the twenty-four hours, may be given safely enough for a month at a time, leaving intervals of intermission from the treatment as long as the secondary group of symptoms last; and this is the practice I have followed for the last twelve months, with the view of preventing the occurrence of the dreaded tertiary stage.

With these brief and very imperfect remarks about the earlier periods of syphilis, I at once pass on to the consideration of that epoch of the disease which constitutes the great and paramount importance of that modern pestilence which is doing so much to embitter the existence of our race. Until recently, tertiary syphilis was but ill understood; nor did John Hunter seem to be aware that the poison might cause these lesions of the brain, liver, kidneys, or nervous system which are now so patent to all of us as being sometimes consequences of syphilis. We find in the tertiary period all the great lesions of syphilis, those lesions which ulcerate the skin, and even attacking the viscera, lesions which put an end to life; and by the term tertiary syphilis I mean that group of manifestations which take place a long time after the primary lesion, which are

not hereditary, and are never contagious, like the lesions of the secondary stage.

Causation of Tertiary Syphilis.—As a general rule it may be said that syphilis tends to arrive at the tertiary period; but all cases of syphilis do not exhibit tertiaries. It would then be of the greatest importance if there could be laid down some prognosis as to what cases are likely to escape them. It has been asserted by Dr. Diday that when the secondary eruption is mild and the induration of the primary lesions slight, we may expect that tertiary lesions will not appear, or be benignant in character. "Tertiary syphilis (according to Diday) ought not to be considered as one of the periods of the disease. It is a pathological condition, distinct in itself, the treatment of which and its clinical characters differentiate it sufficiently from the secondary stage. Its appearance is not due to any excess in duration of the secondary period, for a given case of syphilis may persist for three or four years in the form of secondary lesions, without, on that account, passing into the tertiary stage."

As to Dr. Diday's remark, that cases where induration of the primary lesion was slight or the secondary eruption ill-marked are likely to have no tertiary stage, my own experience has taught me to regard this as a most misleading and faulty induction from experience. Some of the worst and most fatal cases of brain disease I have witnessed, or of ulceration of the soft parts, have supervened after extremely mild secondary eruptions. Indeed, so much is this the case, that some authors have been found to adopt the opposite belief, and to assert that it is precisely these cases of primary sore which are least well-marked, and scarcely followed by any visible secondary eruption, that give serious examples of tertiaries. This view, however, I can neither confirm or reject.

There are, however, some circumstances which I believe do render the prognosis of syphilis in its early periods more grave, as to the occurrence of the tertiary stage. Among these I would enumerate, first of all, old age, then scrofula or consumptive tendencies, then drunkenness, bad living, and other lowering agencies. Numerous examples of these being antecedents of tertiary syphilis occur to my mind; and the question of sex, also, is not by any means to be left out of account, since my experience shows me that women suffer much more from tertiary syphilis than men. And, yet, granting all these as predisposing causes, who is there who has not met with grave and even fatal cases of tertiary syphilis among persons whose constitutions and general health left nothing to be desired?

We cannot prevent scrofula; old age is beyond all remedy; and the evil effects already produced by alcoholic poisoning are beyond our control: but there is another point worthy of all consideration, in the question of the causation of tertiary syphilis—I refer to the treatment made use of in the earlier stages. I will narrow the matter still further, by putting the following categorical question: Does the administration or non-administration of courses of mercury have any effect on the non-appearance of the tertiary stage?

To this very important question the replies have been most different. Dr. Diday in his "Histoire Naturelle de la Syphilis," note v., p. 271, asks whether the appearance of tertiary lesions is due to the absence of specific treatment, and says: "No, again, independent observation teaches us that that tertiary syphilis comes on as frequently after the omission as after the employment of specifics during the secondary period."

Another opinion held with tenacity by the late illustrious Mr. Syme, and by Dr. Hughes Bennett, is, that the chief cause of the occurrence of tertiary lesions is the administration of large doses of mercury in persons already poisoned and weakened by the virus of syphilis; and I confess to have held this view in a modified form for some years, until convinced by experience that tertiary syphilis comes on when all mercury is abandoned, and that frequently enough.

I am not aware that any very distinct statement of the

third opinion has been made in this country of late years, although it used formerly to be held by many practitioners of experience. That opinion is, that the main cause of tertiary lesions appearing is the omission of courses of mercury from the earlier periods of the disease.

Dr. Theophilus Ricord, however, and his illustrious pupil, Dr. Alfred Fournier, have recently been very firm in the position they have assumed as champions of prolonged courses of mercury, in every case of true syphilis, whether mild or not, coming before them, commencing from the period of the indurated sore, as the grand means of warding off tertiary syphilis altogether.

M. Ricord, in his well-known address, delivered a few years ago at the request of Mr. Acton, in the summer meeting of the British Medical Association at Birmingham, said that he gives invariably a six-months' course of small daily doses of mercury to all his syphilitic patients, following this up by another six-months' course of the iodide of potassium. If his patients will not carry out this prescription in its entirety, he bids them seek another adviser.

Dr. Alfred Fournier asserts that "the true cause of the passage of syphilis into the tertiary stage is doubtless the absence or insufficiency of treatment. Whatever certain authors have affirmed, syphilis, when neglected, has every chance of arriving at the tertiary period; and, according to daily experience, the consequences of expectation applied to syphilis are truly disastrous." ("Lectures on Tertiary Syphilis," *La France Médicale*, May 23, 1874.)

In a former series of lectures I listened to in 1871, Dr. Fournier said: "The most simple prudence obliges us to keep ourselves on guard in all cases to advise a treatment sufficient to attenuate, if possible, the effects of the diathesis in the present and for the future. . . . My intelligence refuses obstinately to comprehend how a remedy can moderate all the effects of a poison and pursue this poison through all the organs where it pleases itself to hide, can cure even successive manifestations and discrete symptoms of the diathesis, without in any part finding itself in relation and in conflict with the principle of the diathesis, and with the organic cause of these symptoms. Ninety-five cases, in one hundred in my notes, show me that syphilis, when treated, is usually benignant. Among syphilitic patients treated by mercury, not five per cent. are rudely attacked. . . . When not treated, syphilis is most dangerous, and we have too often to remark on our patients the evil effects of expectation in syphilis." ("Leçons sur la Syphilis," p. 1035.)

According to Dr. Fournier, mercury cures iritis, syphilitic psoriasis, and neuralgia, and acts on the diathesis. He alleges that syphilitic patients, when untreated by mercury, may have complete alopecia, loss of vision, and loss of the palate; whereas in patients carefully treated for many months (and he recommends intermitted courses of six weeks at a time during two years, giving ten months of small doses of mercury to all syphilitic patients as a prophylactic against tertiaries) there are only observed some superficial symptoms and slight alopecia. Relapses are slight, too, and rarely indeed do severe accidents show themselves; so that, if we count, we shall find how many more severe cases there are when mercury is not used. This was in reply to the argument of Dr. Després, who, in 1867, brought before the Société de Chirurgie of Paris long statistics of cases of tertiary syphilis, all of which had been treated by courses of mercury for their early stages by the first authorities in Paris.

(To be continued.)

By telegram we learn that Professor Willis, Jacksonian Professor of Natural and Experimental Philosophy at Cambridge, died early on Monday morning. His state for some time past has been such as to create serious apprehensions, and the duties of the chair have been performed by deputy. The venerable professor was seventy-five years of age.

Hospital Reports.

THE LONDON HOSPITAL.

(Cases under the care of Mr. HUTCHINSON.)

THE following case is of interest on account of the very extensive disease of the kidney which had evidently existed for a long time, whilst the patient continued in the enjoyment of what he regarded as his usual health.

The man was acting as an able-bodied seaman at the time the accident occurred which brought about his death, and he had never suffered from any renal symptoms. His accident was a severe one—compound fracture of the leg, yet he bore up under it for some weeks in a manner which was remarkable, considering the fact that he had little or no renal tissue left. No doubt, in the end, his death was caused by his kidneys, yet until within a day or two of his death, when delirium occurred with tendency to coma, there was no reason to suspect their disease.

The case is not by any means without its parallels, indeed, we believe it is the rule in the curious malady known as "cystic disease of the kidney" for symptoms to be wholly absent until just before the fatal termination.

The causes of cystic disease are not understood, but it is generally acknowledged that dropsy seldom occurs during its course. Both kidneys are usually affected by it, and several cases are on record in which both were totally disorganised, and which, therefore, present close parallels to the one which we now record. Mr. Hutchinson, in some clinical remarks on the case, observed that occasionally in other forms of kidney disease the same abeyance of symptoms until within a very short period of the patient's death was observed. He said that the man's case had reminded him of one which came under his observation many years ago at the York County Hospital. A maid-servant was admitted for symptoms which were supposed by a very sagacious physician to be merely hysterical. She had kept her place and done her ordinary work up to the time of her admission. Her most remarkable symptom was the liability to pass into a state of coma, and to remain for several hours in a state from which she could not be roused, and then suddenly to wake up and walk about the ward. At length, in one of these attacks, she died, and at the post-mortem the kidneys were found extremely atrophied; all trace of cortical structure had disappeared, and one of them weighed only a few drachms. This patient had never had any form of dropsy, and had been considered to enjoy fair health until about ten days before her death.

It may add to the interest of the following narrative to state that an excellent wax cast of one kidney is preserved in the London Hospital museum. It shows the organ very greatly enlarged, and wholly converted into serous cysts, many of them as large as marbles.

Compound Fracture of the Leg—Cystic Disease of the Kidneys in very advanced stage—Death in sixth week.

Alexander King, æt. 41, a seaman, was admitted into the London Hospital, under the care of Mr. Hutchinson, March 16, 1870. Five weeks previously he had been injured severely by a wave breaking over him while steering his vessel. He sustained a compound fracture of the left leg. Splints were applied by the captain of the vessel, and a pad placed over the wound. Owing to severe weather they were detained at sea on short provisions till the time of his admission. The wound was only dressed once. On admission it was found that the bones had not united, the wound was not of large size, and the leg could be placed in a fairly straight position. The tibia, however, was bare and white for some two inches above and below the wound. It was a question as to

whether amputation should not be performed at once; but it was determined to wait a little while and see whether he would improve with good diet and attention to cleanliness. His temperature was 99°0', and his pulse 120, and feeble. His tongue was clean, but tremulous, and though he spoke with energy he did not seem in a favourable condition for any operation to be performed. In the evening his temperature was 102·7°, his pulse 148, and his respirations 18. He had had no rigor. During the next few days there was some improvement in the condition of the wound. The soft parts were becoming adherent to the bone, and the wound contracting. It seemed as if it were quite possible for the bone to necrose and separate. His temperature, however, remained high. On the 17th it was 100·4°. On the 18th, morning 99·7°, evening, 101·8°. 19th, evening 103·6°. 20th, evening 102·4°. 21st, morning 99·0°. 23rd, evening 101·3°. 27th, 101°. At this date he became delirious; every now and then he would begin to talk very incoherently and loudly about his voyage, his accident, &c. He did not actually attempt to get out of bed, but threatened to do so. His skin was sweating, and his tongue tremulous, but clean. He knew those of us whom he had seen take notice of him, and called us by name. On the 28th, in the evening, while much the same, chloral was given him, with the effect of quieting him at once, but only for a time. The doses were repeated, and his temperature sank from 100·4° to 98·4°. As he seemed weaker on the 29th however, though quiet, it was considered advisable not to continue the chloral. The delirium became of a muttering kind, his temperature rose from 98·4° while under the influence of the chloral to 101°, then 104°. Then 104·2° during the 29th, 30th, and 31st. On the 1st April he gradually became less sensible, even when spoken to, passed into a comatose condition, and died.

At the post-mortem examination, conducted by Dr. Hughlings Jackson, no changes of note occurred in any of the viscera save in the kidneys. These were in a condition of advanced cystic degeneration. The two kidneys looked exactly alike; the weight of one only was tested, it was two pounds all but an ounce. The ureters were of normal size, but contained a purulent-looking fluid. The bladder was quite healthy, and contained a quantity of moderately clear urine floating over a thicker purulent portion. On testing, a large quantity of albumen was found. The fluid in the cysts was also highly albuminous. The urethra was free from obstruction. The liver and spleen certainly contained no cysts apparent to the naked eye in section.

It is interesting to note that when the man was admitted, the question of how far his condition might be due to scurvy was discussed. His gums were somewhat spongy, and the granulations about the wound had a spongy, unhealthy look, and bled very easily. He had had no meat of any sort for a long time; since his accident he had neglected to take lemon-juice (of which there was a supply). The entire absence of any attempt at bony union was remarkable, and might have been explained on the hypothesis of his suffering from commencing scurvy. There were no extravasations. It is to be regretted that his intestinal canal was not examined after death.

When the delirium came on its nature was very doubtful, whether in connection with the accident at so remote a period (traumatic delirium), or whether due to cessation of the stimulus of rum, of which he had taken a great deal on board ship. He was, however, ordered brandy, as he preferred it, from the first. It is also worth noticing, that despite his evidently serious condition, he did eat meat, and the condition of the injured parts gave more promise of reparation. Suppuration was becoming of a more healthy character. There was no suppuration appreciable on admission. It was fully intended that amputation should be performed if his state warranted it. The very suspicion of scurvy in the first instance was a reason for delay.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

MONDAY, FEBRUARY 15.

VICTOR DE MERIC, Esq., F.R.C.S., President, in the Chair.

DR. HABERSHON read a paper on

OBSURE ABDOMINAL DISEASE.

The author related three cases which had been brought before his notice. The first was one of tuberculosis, ulceration of the cæcum, with perforation and an abscess passing upwards towards the ascending colon. The patient was a man aged fifty-four, who had suffered from double hernia. The disease was regarded at first as hepatic abscess. The man became rapidly emaciated, and died from exhaustion at Guy's Hospital. The post-mortem showed old pleuritic effusion and tuberculous patches in the small intestine; the cæcum was perforated near its base, corresponding with an abscess extending to the under surface of the liver; there were two old hydatid cysts in the liver, the outer walls of the cysts being calcareous; the mesenteric glands were enlarged, the kidneys fatty, and the spleen healthy. The second case was one of inflammation of the colon from the presence of cherry or plum stones, followed by perforation and ulceration. The patient was a man aged forty-nine, who complained of pain below the liver, in which situation a lobular swelling could be detected, separated with difficulty from the liver. The autopsy showed a large portion of the liver adherent to the abdominal wall, and a cavity in the peritoneum containing four plum stones and the kernel of another, which had evidently lodged years ago in the colon, gradually producing perforation. The cæcum was most firmly adherent at the under surface of the liver. The third was a well-marked case of leucocytæmia complicated with hydatid of the kidney, and subsequently with severe epistaxis. After death the sinuses of the dura mater were found to be filled with a green pus-like fluid, as also the veins of the choroid plexus and the tympanum; the lungs were healthy; the tissues in the posterior mediastinum were infiltrated with pus; the heart was not fatty, but full of clots; the liver weighed 97 ounces, and the spleen 102 ounces; the right kidney was enlarged, and the left contained the hydatid cyst; the left ureter contained a calculus, another being found in the bladder. Dr. Habershon remarked on the fatal epistaxis which took place in this case, which was followed by a vigorous and interesting discussion and Dr. Habershon's response.

Dr. C. R. DRYSDALE then read a paper on

THE ANTECEDENTS AND TREATMENT OF TERTIARY SYPHILIS, which will be found at page 179.

EARLY IRISH MEDICAL LITERATURE.

An interesting communication on this subject has recently appeared in the *Irish Builder*, which is well worthy of notice in our columns.

A knowledge of Greek and Roman practice in the healing art appears to have been known at a very early period in the history of this country. Though it may not be known to our English professional brethren or the general public, numerous MS. tracts are still in existence which prove that among the class of men who followed the healing art in Ireland, in early times, were men who could favourably compare with those of any other nation.

In 1794 Dr. Samuel Crumpe, M.D., of Limerick, a well-known popular medical practitioner, a member of the Royal Irish Academy, and an author of some note in his day, drew attention in the *Anthologia Hibernica* to "A manuscript copy of the 'Aphorisms of Hippocrates, and an Irish Commentary thereon.'" Dr. Crumpe said that his learned friend, Dr. Sylvester O'Halloran, author of a *History of Ireland* and other works, mentioned to

him that he was in possession of an Irish manuscript of the "Aphorisms" alluded to. Dr. Crumpe describes this MS. work as executed on thick vellum, and the manuscript containing two different performances, both imperfect, and each evidently written by a different hand. He describes one as composed of extracts from the *Coacæ Prænotiones* and *Prognostics* of Hippocrates, to each of which was annexed a long Irish commentary which he said he could find no person able to translate. The other consisted of some of the Aphorisms of the same author with a similar concomitant commentary.

The commentaries are described in general very long, and the one published by Dr. Crumpe in the *Anthologia* in Irish type is described to be an uncommonly short one. In his opinion the translation of the Greek was tame, and in some places ungrammatical, and in general as closely literal as the different idioms of the two languages would allow. With the Irish commentary Dr. Crumpe confessed that he was entirely unacquainted, and left it to others to determine the age and the probable author of the MS. work.

Shortly afterwards Mr. Theophilus O'Flanagan, of Trinity College—"a novice in medicine" at that time, but possessing an acquaintance with the Irish language—undertook to set Dr. Crumpe and the public right on the subject. In his communication to the *Anthologia* he begins first by giving a translation of the Irish Commentary, but, from "motives of delicacy," he gives it in Latin. It may be worth reproducing this translation now, not from its medical value, but from the historical interest attaching to it:—"Etenim quod hic indicatur, hoc est. Si Mulier, dum gravida, febre corripitur acuta, mortale erit. Hoc etiam de aliis in universum acutis morbis intelligitur, uti sunt morbi Tetanus et Apoplexia: Hi enim morbi existunt interdum sine febre, aliquando etiam febre comitante. Cum autem febris comitatur, melius est mitem adhibere diætam, uti febris requirit; si autem hoc factum sit fœtus occidetur, et etiam si diæta tunc temporis datur, febris causa quoque augebitur, et fœta et lætus occidentur. Et indicatur itidem quod, si fieri possit, bonum fuerit eorum alterutrum legitimis sanari diætis."

This is a very literal translation of the Irish into the Latin. On consulting some editions of the Aphorisms, Mr. O'Flanagan said he met no comment bearing an equal similarity to that in question with one of Heurnius, published in 1611.

There appear to have been many copies of comments on the works of Hippocrates, Galen, and others, and we believe that among the MSS. of Trinity College they will be still found with other long-unnoticed medical tracts.

Writing in 1794, Mr. O'Flanagan said that there was formerly in the hands of Dr. M'Mahon, of Tureen, in the County Clare (father of the once celebrated Thomas O'Brien M'Mahon), a very curious medical tract entitled "Lilium Medicinæ" (an "Irish book with a Latin title," as someone has expressed it), transcribed at Montpellier in the beginning of the eighteenth century. The first association of the faculty at Montpellier is claimed for a society of Irish physicians.

Mr. O'Flanagan had no doubt as to the genuine and direct originality of Dr. Crumpe's manuscript, or that it was by a practitioner; but as to whether an empiric monk or mere regular adept, he thinks it was the latter, as this country had physicians in abundance, and they formed a separate and distinct order of men in the State, as they do at the present day. The date of the work would answer any period from the seventh or eighth century down to the suppression of the Irish language by English acts, and the consequent neglect of native literature.

A perusal of "Cormac's Glossary," a translation of which has been given by the late Dr. O'Donovan, ought to convince any sceptic that the state of learning in Ireland long previous to the tenth century was very advanced indeed, and that the medical as well as legal knowledge of Irishmen was not only commendable, but remarkable.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 3, 1875.

THE DUBLIN HOSPITAL SUNDAY DISTRIBUTION.—III.

IN our two preceding articles on this subject we endeavoured to show that the system adopted for the distribution in '74, and re-enacted for this year, is partial and inequitable, and very far from being calculated to attain the largest result in the way of medical relief of the destitute poor which the donors of the Hospital Sunday Fund are entitled to receive. We sustained this proposition on the ground—*firstly*, that by the unfair advantage given to "subscription" hospitals, that class of institution had received and would receive an utterly disproportionate share of the Fund; *secondly*, that the Fund was not distributed to those hospitals which afforded the largest amount of medical relief to the poor, or apportioned in ratio of the amount of useful work done by each hospital, but was, on the contrary, lavished on hospitals which did little, to the neglect and injury of those institutions which bore "the burthen and heat of the day."

We called attention to the fact, as shown by the Council's Report, that though the City of Dublin Hospital got credit for no extern accidents at all, nor any extern midwifery cases, yet it received £408 for its "work done," while Mercer's, which presented a record of 2,182 extern accidents, received only £141, Steevens', with its 1,466 accidents and 105 extern midwifery cases, only £114, and Sir Patrick Dun's, with 624 accidents and 523 extern midwifery cases, only £88.

For their vast work amongst the extra-hospital poor

Mercer's only received credit for 2·18 beds, Steevens' 1·67 beds, and Sir Patrick Dun's 1·68 beds. In fact, as we have before said, as far as participation in the Fund goes, these hospitals would have been just as well without their extern departments.

We proceed now to establish—if we may do so to the satisfaction of our readers—that the system of distribution has failed to take cognisance of the question of the economic administration of the hospitals which are subsidised from the Sunday Fund. As we stated in the first instance, "our principal object in calling attention to the subject is, however, to protest against a system of distribution which takes little or no cognisance whether an hospital is administered with careful economy or with gross extravagance, which, in other words, takes no care that the Hospital Fund shall go to the sick poor rather than to unnecessary salaried officials. We maintain that the first duty of the Council is to see that the money shall produce the maximum amount of relief to the destitute sick themselves, and that the least proportion of it shall be applied to objects which afford them little or no benefit; when we tell our readers that in some of the hospitals which received a considerable share in the Fund more than three-fourths of the money goes in establishment expenses (the gain from which is hypothetical)."

This is a statement which, if true, is certainly deserving of the earnest attention, not only of those who distribute the Fund, but of everyone who contributes to it, and it touches so nearly the propriety of the entire Hospital Sunday movement that, if untrue, it ought to be immediately refuted. . . . That our readers may satisfy themselves as to our justification for it, we reprint here the statistical statement of the cost of various hospitals, furnished partly by the report of the Dublin Hospital Board to Parliament, and partly by the returns of the Hospital Fund Council. The following table gives the

AVERAGE COST PER BED FOR MAINTENANCE AND FOR ESTABLISHMENT.

NAME OF HOSPITAL.	Average daily number of Beds occupied throughout the year.	Average annual cost per Bed for Maintenance.		Average annual cost per Bed for Establishment, exclusive of buildings and furnishing such buildings.		Average annual cost per Bed for Maintenance and for Establishment exclusive of buildings and furnishing such buildings.	
		£	s. d.	£	s. d.	£	s. d.
Westmoreland Lock	56·71	12	1 6½	29	8 11½	41	10 6
Steevens's	125·81	23	0 7	17	16 7½	40	17 2½
Meath	90·07	21	15 9½	16	1 4½	37	17 2½
Cork Street	41·75	23	7 11	65	4 11½	88	12 10½

UNSUBSIDISED HOSPITALS.		Average cost for both per bed.					
		£		s. d.			
Sir Patrick Dun's	43·01	70	0 0			—	
City of Dublin	53·04	46	9 2			—	
Mercer's	48·00	43	19 3			—	

* Maintenance comprises provisions, groceries, alcoholic stimulants, drugs, leeches, surgical instruments, medical appliances, and clothing of patients.
 † Establishment charges include salaries of officers, wages of servants, rations of officers and servants, clothing of servants, rent, taxes, insurance, soap, candles, fuel, gas-light, furniture, repairs, straw, bedding, utensils, buildings, and furnishing such buildings, stationery, printing, advertising, burials, coffins, pensions, incidentals, and laundry expenses.

What does this table teach us? It shows us beyond a doubt that, excluding the special institutions, such as the Lock, the Incurables, the Lying-in, and the Ophthalmic Hospitals, it costs nearly £90 in Cork Street Fever Hospital, and £70 in Sir Patrick Dun's, to do the same work which is done in the Meath for £37, in Steevens' for £40, in Mercer's for £44, and in the City of Dublin for £46. We ask, is this a comparison which should have been ignored by the Distribution Committee in the past year, and should be thought unworthy of notice in the coming allocation of the fund? It is by these statistics placed beyond dispute that the Hospital Fund can practically maintain two beds in the Meath, Steevens', Mercer's, or the City of Dublin, for one which it can keep up in Cork Street, or in Sir Patrick Dun's—in other words, that every £1 given to these latter institutions does as much work as £2 allocated to the more expensive hospitals.

But it has been said that to assess the share of the fund to each hospital in proportion to the economy of its working would be "to put a premium on the starvation of the patient." Let us see whether the foregoing table justifies such a statement. An appeal to its figures will satisfy us that there is no truth whatever in the insinuation that in the cheaper hospitals the patient is restricted either in the quality or quantity of his food, drink, or medical comforts. Let us remember that Cork Street, being a fever hospital, is supposed to be lavish in its expenditure upon wine, eggs, brandy, and the most expensive forms of nutriment; yet out of the £88 which the bed costs, only £23 is absorbed by the patient, while the Meath is able to afford to give him or her £21 out of £37, and Steevens' £23 out of £40. It is thus evident that the patient is just as well provided for in either of these hospitals as in Cork Street or Sir Patrick Dun's, although the actual maintenance of the bed is only one-half.

To establish this fact more perfectly we append the full diet scale of Cork Street and Mercer's Hospital, and we ask our readers to judge whether the patient does not fare quite as well in the bed which costs £43 as in that which costs £88.

FULL DIET SCALE.

		<i>Cork Street Hospital.</i>	
BREAKFAST...	{	Half-a-pound bread,	
		Three-quarters pint tea.	
DINNER ...	{	Half-a-pound bread,	
		Half-a-pound boiled beef without bone,	
		One pint broth.	
SUPPER ...	{	One pint flummery, or rice,	
		Two-thirds pint new milk.	
		<i>Mercer's Hospital.</i>	
BREAKFAST...	{	Half-a-pound bread,	
		Three-quarters pint tea.	
DINNER ...	{	Half-a-pound bread, or	
		One pound potatoes,	
		Half-a-pound boiled beef, with	
		Three-quarters pint broth.	
SUPPER ...	{	Quarter-pound bread,	
		Three-quarters pint tea.	
ON FRIDAY...	{	Six ounces bread,	
		Three-quarters pint gruel, instead of	
		potatoes, beef, &c.	

But if our readers be puzzled by these statistics, he has not far to look for where the balance of the £88 or the £70 goes.

The table we have printed above will show them that the "establishment" costs in Cork Street £65 per bed, and in the Coombe £50, while in Steevens' it costs £17, and in the Meath £16. The foot-note to the table explains what is meant by establishment; but as our readers can imperfectly comprehend the real causes of this monstrous extravagance of administration we reproduce another table, which gives the—

* 137 patients from the Rotundo and 41 from the Coombe discharged not in labour.

Do the Distribution Committee or the public realise what these facts signify ?

Of every pound given by the Hospital Council, the establishment charges absorb (exclusive of buildings).

	s.	d.	s.	d.
In Cork Street, about	13	0,	and maintenance about	7 0
" Coombe Hosp. "	13	6, "	" " "	6 6
" Rotundo "	10	6, "	" " "	9 6
" Steevens' "	5	0, "	" " "	15 0
" Meath "	4	6, "	" " "	15 6

If we turn to the statistics furnished to the Hospital Council we derive information on this point in greater detail. We find a heading of "salaries and wages" in the column of expenses of maintenance, which we take to mean nurses' and servants' wages and matrons' salary, and that of the medical officers, in cases in which any of them are paid. In Cork Street Hospital this item absorbs £940 a year, with 41 beds and no extern department ; while the next highest expenditure for this department is at Steevens' (£438) with 126 beds, a large dispensary, and an extern maternity, and the City of Dublin, with its 53 beds, only costs £263 for "salaries and wages." But this £940 is far from representing the expenditure on officials in Cork Street. for we find under the column devoted to "Management" that £682 more goes to salaries in this hospital and the Coombe, which can only afford £185 to feed its patients and maintains only 17 beds, pays £388 to its officers, while Mercer's with its 48 beds, pays only £322

for all salaries and wages, whether connected with maintenance or management.

Is it unreasonable in us, speaking for the public and for those who are doing all that in them lies to apply their hospital income to the best advantage of the patient, to complain that the Hospital Council has blindly paid over its pounds to Cork Street, and other extravagantly managed hospitals, and has omitted to give any credit whatever for Economy of Administration ? That last phrase signifies more beds maintained, more patients relieved, and more good done with the grant, and the Council, in refusing to look to this side of the question, have to some extent vitiated the results which the benevolent had hoped to attain.

Having felt ourselves called upon to condemn in strong terms the system of distribution, and to declare that it is neither equitable nor efficient, we trust we shall not be understood as desiring either to discourage the Hospital Sunday movement or to disparage the benevolent services of those gentlemen who have devoted so much energy to carrying it into effect. When the suggestion for such an effort was made some years ago by Dr. Henry Eames, we were glad to lend every influence in our power in its favour, and we have always regretted that so noble a movement should have been impeded as it has been. We trust that what we have said will be accepted not as a declaration of hostility, but as warning to the Council not

to be led by the voice of anyone, but to investigate for themselves the truth of our statements, and, if our complaints seem reasonable, to act upon our suggestions. Nothing will tend to establish the movement on a firm basis, or to stimulate the public charity so much as the knowledge that every shilling given to the Fund produces the utmost value to the sick poor which it can possibly be expected to yield.

THE WORKHOUSE AS A SCHOOL OF MORALITY.

It is nothing new to social science inquirers to be made aware that our workhouse system, though a necessary and important means of relief to the destitute, is in some respects the subject of gross abuses and the mother of great evils. Not the least amongst these evils is the maintenance in idleness of the worst class of women, who not only prey in large numbers upon the State charity, but are the means of polluting the minds of those whom destitution may drive to seek shelter in the union. We have, in a recent report of the Enniscorthy Police Sessions, an evidence of the depth of degradation to which such wretches may fall, for we find them prosecuted for robbing their own children of the too scanty nourishment which the workhouse affords them. Four women were summoned by the guardians "for that they, at Enniscorthy workhouse, having the care and custody of their children, under the ages of four years, did then wilfully, maliciously, and unlawfully refuse and neglect to give their children necessary food, to wit, sweet milk, found and proved by the complainants, and entrusted to the defendants for the nourishment, maintenance, and support of their children, whereby the health of the children was injured; and on a second charge, for stealing the milk of complainants."

It was sworn by one of the witnesses that eighteen days ago she saw the three last-named defendants with a bottle containing the milk which was supplied to them for the use of the children, and they churning it by shaking it until butter came on it; that they then took it off and used it, giving some also to their children.

The medical officer gave evidence to the effect that for some time past he observed the children of the Enniscorthy workhouse not having the healthy appearance that the food supplied to them would lead him to expect, and he now attributed their delicate appearance to the practice of their mothers churning the milk supplied for their own use, and depriving the children of their natural food.

The four women were sent for trial, and we trust will meet with the retribution which their selfish barbarity entitles them to.

MR. CROSS'S BILL.

THERE is at present arising throughout England a most laudable persuasion on the part of the richer and better-educated section of the community, that the lot of the labouring classes in our large hives of industry is very far from being satisfactory. Pauperism is excessively common, and drunkenness lamentably frequent. England, too, is, in comparison with Ireland, in a most perilous position with respect to the way in which the poor laws are administered; there being in England a complete oblivion of the fact that out-door relief is the very best way to break down all independent feeling among the working classes, since it frequently makes the lot of the idle vagabond superior to that of the toiler, who is obliged to be continually looking about for work, whilst the lazy recipient of out-door relief sees himself and his family supported, in far too many instances, without the slightest trouble or anxiety. They do these things better in Ireland.

Mr. Cross, in introducing the Artisans' Dwellings Bill, has shown that he has taken considerable pains to make himself acquainted with the home-life of the poorest classes in our overgrown manufacturing towns. In introducing the measure, the mover of the Bill observed that, although much has been done by private enterprise to ameliorate the dwellings of the working population, accommodation has only been provided for some 30,000 persons, whilst the population in London has been increasing at the rate of 40,000 a year. He argued that the State has a bounden duty to see that the health of the community should be as high as possible, since it is not only the present generation which suffers by the miserable physical conditions in which poor people live, but unborn generations are rendered diseased and puny on account of the wretched dwellings of their parents in the present.

Mr. Cross puts it before the House of Commons that where the death-rate varies from 22½ to 24 per 1,000 in a healthy town district, to 38, 67, and even 70 in overcrowded courts and alleys of large cities, something is evidently very far wrong; and this is abundantly clear. The only question is, can any Government do much to make men live healthier lives? It was shown that in the parish of St. Giles's there were no fewer than seventy streets without any open central road, and where the houses were so constructed that dirt and disease were constantly present, so that the only way to make a change for the better in many cases would be to pull down the tenements, many of which stand on damp ground, whence arise foul air and miasmata.

Liverpool, Glasgow, and Edinburgh are all most unhealthy towns, in the crowded districts inhabited by the poorer classes, and improvements have been made in these cities of late years by driving wide streets through some of the worst quarters. But the houses which have been erected along these streets are reported to be far from being so good as they ought to be; so that, it is urged, when houses are allowed to be pulled down, care should be taken to prevent worthless and ill-built tenements taking their place.

The purpose of Mr. Cross's Bill is to make the City authorities responsible in London proper, the Board

British Army Medical Service.—List of Candidates who competed successfully for appointments in Her Majesty's British Medical Service at the Examination held at the University of London on the 15th February, 1875.

	No. of Marks.		No. of Marks.
Le Motté, G. H.	... 1,989	Mapleton, E. A.	... 1,895
Dorman, J. C.	... 1,985	O'Sullivan, D.	... 1,840
Kellaall, E. W.	... 1,980	Charlesworth, H.	... 1,805
Chester, W. L.	... 1,979	Sharpe, C. E.	... 1,615

Works for the metropolis in general, and the respective town councils of each large town responsible for carrying these schemes into effect. Not that it is intended to give these town authorities the right of imitating the *Préfet de la Seine* in making showy streets when they please; but the working of the Act is to be entrusted to the medical officer of the district, who is to be bound to report concerning any street which is deemed unhealthy. This is a great mark of confidence in the honour and prudence of the medical men of this country; and this has been nobly earned by the conduct of the members of that self-sacrificing and enlightened profession during the past twenty years.

The local authorities, on receipt of the report of the medical officer, are to satisfy themselves as to its correctness, and find out some remedy, by purchasing the ground and providing for as many of the poor inhabitants as are removed by the improvements carried out in the locality.

This is all admirable, and it will at once put a stop to the iniquitous abuses of the rights of property, which have enabled railway companies and other owners of land in cities in the past to throw out thousands of families into the streets, only to crowd into localities already far over-peopled. In future, it will evidently be necessary for any railway company to erect at least as many new houses as it intends to pull down; and thus an immense deal of unnecessary suffering to the working classes will be prevented.

In London, the scheme for compulsory purchase of the land must be submitted for the Home Secretary's approval before it is carried out. He is to pass the measure through the House of Commons, and thus the expense of a private bill will be saved. In boroughs a similar plan is to be adopted by the President of the Local Government Board, and the value of the property taken is to be determined by the English Lands Clauses Act, except where parties agree to be bound by arbitration, whilst the owner is to have the right of appeal to law when he thinks himself unfairly handled by the town councils. The town councils are to have powers granted to them to deal with the land thus acquired, and to borrow money when they need it, but the buildings are to be erected by private enterprise.

Such are the main features of Mr. Cross's Bill, and there is a great deal indeed to be said in its favour, although there are many obvious enough objections that can be at once taken to it. In the first place, it must be noted that the medical officers spoken of are elected by the vestries, and the vestrymen are often owners of property in the parish, so that the medical man will have to report to the men to whom he owes his appointment, who frequently enough will be glad to use all sort of underhand influence to make him leave out of his report tenements in which they are pecuniarily interested. It is to be feared that in many parishes such medical men who evince any great zeal in sanitary reform would generally fail to be elected to the post of medical officer of health, although, of course, some power of appeal might be granted to public medical men when worried by vestrymen with sinister interests.

Another objection to the bill is that, like many other similar bills, it may often do harm instead of good.

It is not impossible that town councils in their zeal for improvement may occasionally prevent cheap enough buildings being created, and thus drive the very poorest classes into still further over-crowding. It must always be remembered that there is a stratum of society at present in all our large towns the members of which would be very frequently compelled to sleep in the streets if the regulations laid down by some of the Health Acts passed of late years were rigorously carried out. It is in such cases questionable whether even the very high death-rates spoken of by Mr. Cross might not be raised, instead of lowered, by sudden municipal interference.

After all, alas! it must be confessed with a sigh, that the power of governments or town councils over the condition of the working classes must ever be very limited in its scope. Governments and town councils cannot make men and women industrious, or sober, or, above all, prudent; and if the working classes cannot be made less fond of alcoholic stimulants, and more prudent with regard to the size of their families, we ask, what bill is there that will ever prevent them from being over-crowded and over-worked?

At the same time, we confess that it is with a feeling of the greatest satisfaction that we observe that public attention is now pointing steadily in the direction of improving the dwellings of the poor in cities.

The condition of the poorest working classes in Liverpool, Glasgow, Edinburgh, &c., is not a whit more desirable than that of the uncivilised inhabitants of some of the most backward nations in the world. Ignorance, misery of all sorts, and disease, are constantly endemic in the wretched courts and alleys of all our manufacturing cities; and we can think of no subject so full of promise as that which discusses the causes and remedies for such frightful phenomena as these. The *religio medici* of this century has long been the turning of all resources of science towards the grand aim of lessening the sufferings and increasing the pleasures of the poor and the weak.

Notes on Current Topics.

A Homœopathic Novel.

AN anonymous author has attempted to seduce careless readers into a consideration of homœopathic principles by presenting these in the framework of a very slight novel. "We should," says the *Chemist and Druggist*, "have welcomed such an innovation with the most sincere joy, and would have swallowed the principles recklessly, if only the tale had been more artistically constructed. The notion of a man losing his sweetheart because he had embraced homœopathic doctrines is too ludicrous even to be worked into a romance, and yet it forms the skeleton of 'Dr. Lowe's Sacrifice.'" In order to make the book look like a novel a certain lot of characters are introduced, all of whom, men and women, discuss the relative merits of allopathy and homœopathy. The advocates of the former symptom of course utter the most stupid ideas, and betray a most shameful lack of

honour, both in their arguments and in their conduct. The homœopathists, on the contrary, are invariably calm, dignified, logical, and successful. In practice the system works wonders. By its aid the hero of the tale is able to cure the most hopeless diseases, to win fame and wealth, and at last to secure the heart of his once faithless *fiancée*. His foes at the same time are dispersed and confounded, and he and homœopathy triumph over all the slanders which have been circulated concerning them.

Quinine Frauds.

In a recent issue we published an extract from the *North China Herald* reporting the seizure of 80 bottles of spurious quinine which had been imported into Shanghai. From the same paper of a subsequent date the following is quoted into the *Chemist and Druggist*:—

"Another instance of importing spurious quinine came under the notice of the Customs authorities lately, the quantity being 100 one-ounce bottles, for a Chinese firm we believe. The shipment was detained on the score of false declaration, and a bottle submitted for analysis. It was at first suspected that the substance would prove to be salicine, which is a frequent adulterant and substitute for quinine, but the application of the usual test failed to indicate any trace of salicine in the sample. Quinine itself, or any of its salts, was equally undistinguishable, and subsequent examinations proved the substance to be composed entirely of muriate of cinchonine, a product of cinchona bark, the market value of which is one-fourth that of quinine, while it possesses remedial qualities analogous but less in degree to those of the valuable medicine for which it is attempted to pass it off."

Adulteration.

"MILK OF SULPHUR" has been the subject of the latest prosecutions in England, the article sold under that name being found by analysis not to be sulphur at all, but half sulphur and half plaster of Paris. The defence, as stated by a member of a wholesale drug firm, was that, during his twenty years' experience, milk of sulphur was known in the trade as an article prepared by mixing together lime, flour, sulphur, and water, and precipitated with sulphuric acid. He had never known milk of sulphur without the presence of sulphate of lime. Under the term "milk of sulphur," sulphur would not be sold without sulphate of lime in it. Precipitated sulphur was known in the trade as a distinct thing, the difference being that it was pure sulphur, and milk of sulphur was not pure sulphur. In other words, it was pleaded that if the customer asked for "precipitated" sulphur he would get the pure, but if he asked for "milk of sulphur" he would get plaster of Paris. But even this defence did not suit another chemist, who had been asked for precipitated sulphur, and, nevertheless, sold sulphate of lime. He said, in defence, that neither the borough analyst nor the court had yet recognised what was an undoubted fact, viz., that there were in commercial circles two kinds of precipitated sulphur—one of the new style and the other of the old style. He trusted that the analyst would himself admit that adulteration meant the act of corruption by admixture with a foreign article, and that being so, it would not be alleged that there had been any admixture in the present instance either by himself or by

the persons from whom he had bought the article. It was, indeed, only just to Messrs. Goodall and Backhouse for him to say that he was supplied with precisely the same article as he asked for. They inquired if he wanted the precipitated sulphur of the British Pharmacopœia of 1867, or what was ordinarily known in the trade as lac sulphuris (milk of sulphur). He of course said he wanted the latter. The terms precipitated sulphur, lac sulphuris, milk of sulphur, and milk of brimstone were synonymous under the old style, i. e., the Pharmacopœia of 1837; but the precipitated sulphur of the British Pharmacopœia of 1867 was another preparation, and was not synonymous with milk of sulphur. He then quoted from Rennie's "Supplement to the Pharmacopœia of 1837," and from Hooper's "Medical Dictionary," to show that lac sulphuris and sulphur precipitatum were then regarded as synonymous terms. He had in his shop the precipitated sulphur of the Pharmacopœia of 1867, but he should never think of supplying it when precipitated sulphur was asked for, unless the customer knew the difference between it and what commonly went by that name.

This culprit was allowed an adjournment to enable him to prove by oral evidence that when asked for precipitated sulphur in 1875 he was justified in selling the preparation which passed by that name in 1837.

The most astonishing aspect of this controversy is that in all the recriminations the unfortunate consumer is totally forgotten. We have abundant evidence that "the trade" know what they mean and what they are likely to get when they ask for milk of sulphur. Probably they have a thorough appreciation of the fact that they are buying 53 per cent. of *pounded* gypsum, but what has that got to say to the consumer, who should be supposed—in common honesty—to get what he pays for. Does he know that milk of sulphur is one half lime, or that "old style" precipitated sulphur is a different thing from "new style"? Not at all! When he asks for sulphur he means to get sulphur, and if he knew he was getting anything else he would demand the return of his money and leave the shop. However the transaction may be obscured by sophistries of the sort we have quoted, it is, intrinsically, a gross fraud perpetrated for the purpose of making money illegitimately, and it is humiliating to see the organs which represent honourable pharmacy trying to wriggle out of the necessity of looking at the matter in an honest, common-sense light.

Manual Dilatation of the Os Uteri.

DR. SINCLAIR (*Boston Med. and Surg. Journ.*, No. 5, 1875) says that from time to time various means have been resorted to in order sufficiently to dilate the uterine orifice to admit the hand into the interior of the uterus. Chief among these have been the sponge tents and the dilators of Keiller and Barnes. To the use of these instruments obstetric medicine has been and will be greatly indebted, particularly in the operation of inducing premature labour. It is evident, however, that the hand of the obstetrician as a uterine dilator may be made a more efficient means, and has claims upon our attention. The hand is always available; it can be easily governed. Whenever a sponge-tent or rubber-bag can be inserted, the finger may be introduced. The hand and the brain

of the operator being in constant sympathy, giving him the precise idea of the condition of the parts, he is enabled to regulate the force necessary to obtain dilatation. Artificial dilators frequently require manual aid to keep them *in situ*. As the skilled surgeon, in the process of certain operations, finds greater safety in the use of his fingers than of the knife, so may the obstetrician substitute his hand for artificial means as often as practicable.

He gives the case of a primipara who, on the 18th of January, 1870, being seven months pregnant, had been seized with frequent and severe convulsions for ten hours, the severity of the seizures having been alleviated by chloroform, but the attack having returned with unabated violence on leaving off the anæsthetic. She had passed no urine for twenty-four hours, and that obtained from the bladder was very albuminous. The lower extremities were much swollen, and the case was looked on as one of great danger. The induction of premature labour was advised, as it offered the greatest safety to the patient. The patient was chloroformed. The hand being oiled, a finger was passed into the orifice of the vagina, which was small, but after a time it yielded to gentle pressure, so as to admit the whole hand. In the same manner entrance to the os uteri was effected. Although the opening was at first so small as not to admit the point of the index finger, the exertion of gentle force effected an entrance. He waited until the cervix relaxed, and passed another finger, and, lastly, all the fingers, shaped like a cone. Lastly, the whole hand could be introduced into the uterus. The child was turned, and is now living. The operation took an hour and a half. The patient made a good recovery.

Male Sterility caused by Syphilis.

DR. LAROYENNE (*Lyon Méd.*, Jan. 24, 1875) says that, besides malposition of the testes, gonorrhœal orchitis, and neoplasms due to syphilis and tuberculosis, we are scarcely acquainted with, in the male, any other causes of sterility which are unaccompanied with impotence. He thinks that syphilis is another cause, syphilis without any lesion of the testes or cord, clearly to be seen at the bedside. He does not contest the frequency of abortions or of congenital syphilis arising from the father. This assuredly testifies to the persistence of the power of fecundation in the greatest number of patients who formerly were infected. But whilst taking this into account, a close observation of syphilitic fathers shows that their union is often sterile, more frequently, all things considered, than in those who have not had the disease. He speaks of tertiary syphilitic patients. The evolution of the diathesis has been manifested in them in spite of treatment or because of its insufficiency. Having had to examine, on account of their sterility, the wives of a certain number of syphilitic patients, he found five of these in whom the condition of the uterine organs was apparently quite normal. One of these ladies had been married three years, the others six, seven, twelve, and thirteen years. The epoch of the disease dated from four to ten years previous to the marriage. All the husbands had had tertiary symptoms. The examination of the semen, which is always troublesome to have brought to the practitioner, will furnish, he is convinced (why did he not try?) the direct proof of

this sterility. He would give iodide of potassium as soon as the hard chancre appears.

In the debate which followed this paper, Dr. Mollière said that Liégois had ascertained the persistence of spermatozooids in the most advanced period of cachectic diseases. Dr. Coutange mentioned a case of a young man with tertiary syphilis and one epididymis hard, and who had no children, but the semen was not examined. Dr. Jullien knew certain facts which showed that men who had children before having syphilis became sterile after infection. Dr. Laure mentioned the case of a man with cerebro-spinal syphilis who had no children.

The Adulteration Act.

THE President of the Local Government Board has issued a sealed order approving of the election of Dr. James Edmunds as Public Analyst for St. James's. The clause in the recent Adulteration Act, by which persons are only elected as public analysts subject to the approval of the Government, constitutes a most beneficial proviso, and one which is the more valuable, as officers thus approved of cannot afterwards be dismissed except with the concurrence of the central authorities. The Act says that the person chosen must be one "possessing competent medical, chemical, and microscopical knowledge," and his duties are to act "as analyst of all articles of food, drink, and drugs purchased within his district." Before the elected officer is approved of, evidence on each of these points is called for. Registerable medical and surgical diplomas seem to be accepted as evidence of the possession of competent "medical knowledge;" but it is now the practice of the Board to call for "further evidence" on each of the other points, and, in particular, for "explicit evidence" as to the candidate's knowledge of chemical science and his previous experience in laboratory work. These very stringent but obviously quite proper requirements have not always been anticipated, and several candidates have recently suffered some humiliation by their failure to meet the requirements of the Government after having been returned by a public election in their own neighbourhood. It is obvious that many very able medical men might feel this to be a difficulty, but, on the other hand, mere professional analysts would be still more at a loss to find evidence as to the possession of "competent medical knowledge." We cannot but think that the office of public analyst is a very proper appendage to the larger and more important one of medical officer of health, and we should be glad to see generally adopted the judicious resolution of the St. James's Vestry to elect only an officer competent to hold both offices jointly, though, of course, there will be many districts, not having the same choice of highly-qualified candidates, where this may not be practicable. It ought to be more generally realised by the public that there is now in every district of London a publicly paid officer who, on payment by the applicant of a nominal fee to the vestry, is bound to analyse and certify upon any sample of food, drink, and drugs that may have been purchased within his district. The Adulteration Act has done immense public service by its mere deterrent effect, while it has also been useful in punishing some of the people who not only cheat, but poison their customers. Were it necessary, however, to prove in every prosecution

that the retailer sold his adulterated goods *knowing them to be adulterated* the Act would be nullified. The sale of cocoa mixtures, of coffee mixed with chicory, of mixed mustard, and of other things which are really a convenience to the public, should be allowed on the simple condition that a label is affixed to each packet stating the ingredients and their proportions. If only purchasers know what they are buying the rule *caveat emptor* may safely be adopted.

Method for Inducing Premature Labour.

DR. BRAUN (*Phil. Times*, Jan. 23, 1875) says the plan he pursues he has found to give the best of all results. It is nothing more than the practice of the original method, consisting in the employment of a pointed quill, or, what will answer the same purpose, a steel pen. This method, besides having the advantage of simplicity, is always applicable, as the instrument is ever at hand. The point of the quill is placed upon the palmar surface of the index-finger, which is then passed up to or through the cervix and the membrane punctured. An improvement on this plan consists in making an opening in the side of the quill, through which a sound can be introduced. The point of the quill is then brought into close apposition with the body of the sound. The latter is then passed through the cervix, the quill being kept in position, and when the desired distance is reached the sound is withdrawn, leaving the quill behind, and the puncture can be made. In this manner we overcome the difficulty of passing the projecting angle of the posterior wall of the cervix.

By this method no damage can result, and a long narrow cervix can readily be passed. As the amniotic fluid drains away, pains are induced, the head passes down, and in twelve hours, delivery can generally be accomplished.

Dr. C. Belluzzi (*Bull. d. Sc. Méd.*, Dec., 1874) thinks the method dangerous to the life of the fœtus. He has used laminaria tents in some cases with advantage, as also sponge tents.

In 1870, Dr. A. Monteverdi, of Cremona, praised quinine as a means of producing premature labour. Dr. Belluzzi has not found this method successful. Sucking of the breasts, recommended by Scanzoni, was found also of no use. The use of electricity also did not prove successful in his hands.

Insanity from Sexual Causes.

THE late Dr. Skae (*Edin. Med. Journ.*) classifies some varieties of insanity as from sexual causes. The *insanity of pubescence* in boys is characterised by a first stage of restlessness, excitement, braggadocio, and pugnacity, followed by one of hysterical depression, with a tendency to exaggerate every petty bodily affection into some dreadful disease. It may assume a religious or cataleptic phase, and may be complicated with or end in *insanity of masturbation*, of which the symptoms are much the same as those described in quack advertisements headed "nervous debility," with the addition of dislike of female society, inability to look you straight in the face, and fear of suicide. This may end in suicidal or homicidal mania, or in a form of dementia, with silly self-satisfaction and vanity.

In girls, hysteric insanity seems to be the counterpart of this *insanity of pubescence*. It is frequently complicated with masturbation, or arises out of it. It is characterised by great excitement, talkativeness, and sleeplessness, and sometimes by fits of screaming and efforts to escape from the house. All these symptoms have an erotic tinge, the patient sometimes imagining that there is something wrong with her uterus, or that she has retention of urine; sometimes, that someone is in love with her, &c. Dr. Skae quotes a very characteristic letter from a young lady in such a condition. Satyriasis and nymphomania are diseases closely connected with the above by *origin*, Dr. Skae thinks, in the nervous centres, not in the generative organs.

Dr. Blandford remarks on the close connection between the various forms of sexual insanity. In the erotic temperament, pubescence leads to masturbation, that to hysteria, and that to amenorrhœa. Dr. Skae gives a case of amenorrhœal insanity in a young married woman in whom it was due to masturbation, originating after child-birth. Insanity arising from masturbation, with amenorrhœa, is frequently suicidal or homicidal.

Lady Doctors.

WE hear that sixteen or eighteen ladies are busy at dissection in London, under the able supervision of Mr. Norton and Mr. Reeves.

Dr. Mary Putnam-Jacobi has been elected delegate to the New York State Society from one of the local societies, and it is intended to send her as a delegate to the next meeting of the American Medical Association.

Mrs. J. G. Brown, M.D., of the Illinois Women's Hospital (*Med. Examiner*) recommends as an effectual remedy for obstinate pruritus vulvæ a solution of sulpho-carbolate of zinc, 30 grains to the ounce of water. After washing with warm water, the solution is applied and left to dry. The application may be made twice a day, to begin with, afterwards once a day, or two or three times a week.

Luxation of the Penis.

DR. MOLDENHAUER (*Berlin Klin. Wochensch.*, No. 45, 1874) remarks that luxation of the penis, on account of a loose connection between the skin and the corpora cavernosa, is an accident which may occur, although not often met with. One case is reported by Nélaton. The patient was a boy who was injured by the falling in of an embankment, the skin around the penis being torn from its attachments, thus allowing that organ to slip under the skin of the scrotum. The displaced organ was restored by slipping a forceps introduced into the preputial opening.

A strongly-built farmer, æt. 57, was injured in October 25, 1867, by falling from his wagon. The horse forced him against a tree, and the hind wheel passing close to the front of his body hurting him grievously. It was found that the symphysis, scrotum, and penis were covered with blood. The penis was much injured, hanging soft and flaccid, as if it had been completely crushed, but not painful. A catheter would not pass the symphysis. There was extravasation of urine into the scrotum. On the 6th November an abscess formed in the abdominal

walls, on a level with the spine of the ilium, which was opened next day and discharged pus very freely, having a fistula whence urine issued. On the 10th November the idea arose that the urethra might be found in the upper inguinal region. A catheter was introduced into the superior opening, which passed down to the opening under the symphysis; and on the 12th an incision was made in the inguinal region, and the penis, deprived of its skin, but in other respects uninjured, was found lying imbedded in the fat and connective tissues covering the muscles of the abdomen. The entire penis had therefore been torn from its cutaneous sheath, and had been slipped up into the inguinal region beneath a portion of the layers composing the walls of the abdomen. The urethra was uninjured: a catheter could be passed from the meatus through the organ, which had formed adhesions to the abdominal muscles up to the symphysis, where its further progress was arrested. The glans and prepuce were dissected off, but, at the request of the patient, who stated that he only wished the penis for the function of micturition, no further attempt was made to restore the organ to its normal state.

Inspection of Hospitals.

THE quarterly court of the Radcliffe Infirmary has decided *nemine contradicente* upon the following resolution:—"That the Government be memorialised to the effect that it is expedient, in the interests of the efficient management of hospitals and infirmaries, to make it within the competence of the managing committee of any such institution, to avail themselves of the services and advice of the sanitary inspectors appointed to act from the Local Government Board, when they judge it to be necessary to do so.

Death of Dr. Thornhill, of the Kilmainham Prison.

WE learn with regret of the sudden death of Dr. William Thornhill, Surgeon to the County Dublin Gaol at Kilmainham. Dr. Thornhill had been summoned to Nenagh as a witness in a criminal case, and was suddenly attacked with something like apoplexy, which terminated his life in a few hours. He is much regretted by the profession in Dublin, having been most estimable in all his relations with them.

By his death the office which he held becomes vacant, and the names of many candidates are already mentioned. We understand that the following gentlemen will probably offer themselves for the appointment:—Dr. J. Hawtrey Benson, of the City of Dublin Hospital, Mr. Stokes, Dr. William Carte, Dr. Wheeler, and Mr. Josiah Smyly. The appointment lies in the hands of the Board of Superintendence, a body of twelve gentlemen of the county, most of them Conservatives, and the salary is £150 a year.

The Regius Professorship of Surgery in the University of Dublin.

THE election to this office, which was vacated by the death of Mr. Adams, and may be regarded as the highest surgical position in Ireland, will take place to-day

(March 3rd). The choice will lie with the newly-elected Academic Council, and the candidates are Mr. Porter, Surgeon to the Queen in Ireland, and Senior Surgeon of the Meath Hospital; Mr. Colles, Surgeon to Stevens' Hospital; Mr. Tufnell, President of the Royal College of Surgeons, and lately Senior Surgeon of the City of Dublin Hospital; and Mr. Wharton, Surgeon to the Meath Hospital, Lecturer on Surgery in the Ledwich School, and Examiner in Surgery in the University.

Compression in Hydrarthrosis of the Knee-joint.

DR. GUYON (*France Médicale*, Dec. 4) says that compression of the knee-joint which has fluid in it is generally made by a thick pad of wadding enveloping the joint, and vigorously compressed by turns of a linen or flannel bandage. This is, on the whole, a rather defective method, on account of the readiness with which the bandage becomes loose. With an india-rubber bandage the same result was to be found, but it is accompanied by the inconvenience of imposing on the patient a circular compression, rapidly becoming painful, on account of the elasticity of the india-rubber. Struck by these difficulties, M. Guyon conceived the idea of substituting for the circular compression of the knee the application of a padded compressive apparatus upon a trough, leaving only the anterior part of the joint uncovered. He proceeds as follows: The limb being placed in the trough, rectangular layers of cotton wadding are applied to the knee, and form, one superimposed on the other, a padding of great thickness. It is upon the trough that the circular bandage is unrolled from which it is evident that the compression affects only the anterior portion of the knee, the posterior and lateral portions being protected by the trough. Thus is avoided the inconvenience and pain so often experienced by the patient from energetic circular constriction, and the compression may be carried much further.

Case 1.—A young man, æt. 19, entered hospital on August 8th with voluminous hydrarthrosis of left knee, which had commenced on the 1st of August. On the 10th the compressing apparatus was applied on the limb, placed in a trough, as above described. On the 20th, the apparatus, which the patient had supported without the least inconvenience, was removed, and hardly any fluid remained. On the 24th, there was no fluid; and on the 25th the patient left hospital cured.

Case 2.—A young man, æt. 32, was admitted on September 29 for abundant effusion into the right knee-joint, of rheumatic origin, and dating back fifty days. On Oct. 4th a blister was applied, which gave no appreciable result. On the 10th the compressive apparatus was applied, and remained on twenty-three days, when, on November 3rd, there was no effusion found.

DR. ASHE, Resident Medical Superintendent of the Londonderry District Asylum, has been awarded the Ryan Prize, value £100, offered about two years since by the Board of Trinity College for the essay that would produce from the Bible the best argument for the truth or Divine origin of Christianity. Dr. Ashe obtained the second Carmichael prize, value £100, in 1868; and the first Carmichael prize, value £200, in 1873.

IODINE CAUSTIC (*Canada Lancet*) is prepared by dissolving 4 grammes of iodine in 8 grammes of glycerine. It is used in lupus by applying it once every other day, and covering the parts with gutta-percha, which treatment is continued for several weeks.

WE notice an excellent review in *Guy's Hospital Gazette*, headed "Some Thoughts on Syphilitic Monomania," wherein the writer shows how exaggerated are the views of Professor Gross and others on the effects of syphilis.

THE late Miss H. Berwick, a niece of the late Judge Berwick, of the Irish Bench, has recently bequeathed a sum of £2,000 to the following charitable institutions, regardless of sectarian differences, viz.:—£700 to the Convalescent Home, Stillorgan (on condition that it is conducted on non-sectarian principles); £750 to the Incurable Hospital; £200 to the Claremont Institution for the Deaf and Dumb; £100 to the Molyneux Asylum for the Blind; £200 to St. Vincent's Hospital; £50 to St. Mary's Asylum for the Blind, at Merrion.

THE evening meeting of the London Pharmaceutical Society will be held to-day. The chair will be taken at half-past eight precisely. The following papers will be read:—On "Lead Plaster," by Mr. C. Umney; on "The Estimation of Fat in Milk," by Mr. E. L. Cleaver.

THE Surgical Society of Ireland will meet on Friday next, at half-past eight o'clock, at the Royal College of Surgeons, when the following communications are set down for reading:—Dr. B. F. McDowel, on "Strangulated Hernia." Dr. Wheeler, on "Pharyngotomy." Dr. C. Fitzgerald, on "Some Peculiar Symptoms connected with Obstructions of Lachrymal Puncta, Canaliculi, and Nasal Canals."

At a meeting of the Council of the Royal College of Surgeons of England on Thursday last, Mr. John Hilton, F.R.S., late President of the College, resigned his seat as a member of the Court of Examiners, to which he was elected in 1865.

THE full-length portrait of Sir William Fergusson, which was painted by Mr. Rudolf Lehmann, and recently exhibited at the Royal Academy, has been presented by the subscribers to the Royal College of Surgeons of England.

THE Chair of Natural History in St. Andrew's University, vacant by the death of Professor Macdonald, has been filled up by the appointment of Professor H. Alleyne Nicholson, F.R.C.S., of the Science College, Newcastle-on-Tyne.

THE Registrar-General reports during the week ending last Saturday 5,573 births and 4,432 deaths in 21 large cities and towns of the United Kingdom. The average rate of mortality in these towns was 29 per 1000.

Literature.

A TREATISE ON CUTANEOUS MEDICINE AND DISEASES OF THE SKIN. (a)

DR. PURDON's multifarious contributions to the medical journals on skin diseases are quite sufficient to constitute him a trustworthy guide on the treatment of these affections. In our judgment he has done well and wisely in collecting his papers and lectures into a handy little volume, arranged for easy reference by the student and busy practitioner.

The author, however, while collecting his own lectures for publication, has not been unmindful of the important labours of others; he has therefore embodied in his treatise the latest views of Hebra, Erasmus Wilson, McCall Anderson, Damon, Neumann (Dr. Pullar's translation), and numerous other well-known authorities on cutaneous medicine. Dr. Purdon has divided his subject for ready reference into twenty-three chapters. Commencing with an historical sketch of dermatology of some interest, he proceeds to treat of the various attempts at classification, the pathological relations of the skin, &c. In the treatment of skin diseases he gives the result of his own experience at the Belfast Skin Hospital, a rising institution for the cure of these affections.

A useful, although too short a chapter, is devoted to the consideration of the pigmentation of the skin in Addison's disease; and that remarkable condition recognised as a neuralgic affection of the skin, and its association with what is termed, for want of a better name, hysteria, is clearly explained and at some length. Dr. Purdon, however, like other practitioners in this branch of the profession, finds neuralgic affections of the skin most intractable to treatment. Of all therapeutic agents tried, he places more reliance on the hypodermic injection of morphia, with the internal administration of bromide of potassium.

With regard to parasitic diseases, Dr. Purdon says: "The part played by fungi in causing diseases is daily becoming more clearly recognised. Few now deny the vegetable nature of many cutaneous affections, but, as may be expected, there are still very various and conflicting opinions expressed regarding them in our modern school of dermatology. No less than four dogmas are held to be indisputable by their various supporters. . . . We must look, however, for an explanation of the differences between the varieties of tinea, not so much in differences of fungus, as of soil and seat upon which they grow. Anyone engaged in a large cutaneous practice must have observed, especially on the body, the occasional recurrence of tinea circinata and favus. I have met with five such cases during the past four years."

With regard to the supposed identity of the vegetable parasites and their relation to a common mould, conflicting opinions also prevail. The attempts made by some dermatologists to split up the fungus into varieties and species for no better reason than that of some trifling difference in the size and form of the spores or the mycelium, scarcely admits of serious discussion. A small and unimportant section of our American brethren cling tenaciously to the identity of the fungus and its specific individuality. We all know, however, that favus is a far more common affection in damp countries and among the badly-fed and ill-nourished than it is in brisk, dry, and temperate places and the well-to-do classes of communities.

In Holland, where it is particularly damp from its numerous canals, in Norway, the north of Ireland, and the west coast of Britain, a comparative frequency of favus has been observed. Only three cases of favus in 10,000 in London is recorded by Erasmus Wilson, and, as Dr. Purdon remarks, "it is perfectly evident that this

(a) "A Treatise on Cutaneous Medicine and Diseases of the Skin." By H. J. Purdon, M.D., Physician to the Hospital for Skin Diseases, Belfast, &c., &c. London: Baillière, Tindall, and Cox. 1875. Pp. 272.

affection is much more common in wet and rainy cities than in those of a drier atmosphere. We also know that low forms of fungoid growths appear with rapidity on preserves, cheese, bread, &c., when placed in damp localities."

Another fact that bears out this view is, the disease is only to be cured by constitutional treatment, plenty of good air, sea-side air if possible, with nourishing food, iron, cod-liver oil, &c.

Dr. Purdon may be congratulated on having produced a useful manual on Cutaneous Medicine.

PHILOSOPHY OF VOICE.

WE need not say very much about this little work, inasmuch as it is reprinted from our own pages. Our readers, therefore, have been able already to form their opinion on Mr. Lunn's views, and enjoy his somewhat pungent criticism. He has very strong opinions on the subject which he has so profoundly studied, and he is desirous that voice culture should be recognised as a branch of the medical rather than of the musical art. We go a long way with him in this respect, but we may inform him that some medical men have paid attention to this subject. In his preface he remarks on the common assumption that the majority of people are created with defective voice, and need a music-master to supplement nature. With characteristic enthusiasm he exclaims, "Monstrous, incredible, and impious assertion! This, on the contrary, is the truth: all error and weakness, and all defect in tone, each and all of these are induced, and can therefore be removed."

Mr. Lunn looks forward to a time when every university will have a professor of voice-production. It is impossible to say if such a measure would prove a remedy for the evils which Mr. Lunn deplures. We regret as deeply as he can the follies of many speakers and singers, who ruin their voices, set up absolute disease in their throats, and give pain rather than pleasure to all cultivated listeners by their unnatural use of the voice.

They come under medical treatment for restoration; but how seldom can they be brought to consider the propriety of prevention?

Mr. Lunn's proposal to hand over voice-culture to the medical profession will undoubtedly lead to much good.

It is not necessary to enter into Mr. Lunn's masterly criticisms of Madame Seiler, Dr. Wyllie, Mr. Curwen, and others; our readers can refer to them at their leisure, and they will find that Mr. Lunn is a formidable antagonist.

As he hits so hard, he ought to be particularly careful in his quotations. We make this remark, because on pages 68 and 69 he holds Dr. Prosser James responsible for some observations which that authority quoted from a foreign writer in his "Reports on Diseases of the Throat" in this journal. As Dr. James repudiated soon after this attempt to make him endorse the opinions he quoted, we think Mr. Lunn, in reprinting his articles, should have corrected his error, which is the more surprising as the profession he thus criticises is well known to have paid much attention to the subject of voice-culture, and might therefore expect to be better understood by a writer of Mr. Lunn's wide information. We have read Mr. Lunn's work with great pleasure, and cordially commend it to the medical and musical professions.

THE MAINTENANCE OF HEALTH. (a)

DR. MILNER FOTHERGILL is favourably known to the profession by an essay which gained the Hastings prize of the British Medical Association. He writes with facility, and clearly. His style is easy, and his work most readable. We doubt not then that this popular work on hygiene will

(a) "The Maintenance of Health: a Medical Work for Lay Readers." By J. Milner Fothergill, M.D., M.R.C.P.L. London: Smith, Elder, and Co. 1874. Pp. 399.

have many readers out of the profession. It is not written, of course, for medical men. The work is divided into thirteen chapters. In the first chapter we have a *résumé* of some of the doctrines concerning the circulation of the blood, and acting and vital force held by modern physiologists. This is a very well written chapter, and it shows that the author has paid much attention to the important subject of physiology, which is the most abstruse part of medical philosophy.

Chapter II. treats of youth—the period of growth; and there are some remarks upon puberty, that dangerous time of life for the male, and even for the female sex, which are worth reading, although Dr. Fothergill, in common with all English writers on sex, is rather conventional in his treatment of this difficult point in hygiene. He does not, for instance, give any indication of being aware of the researches of Bertillon as to the dangers of marriage before twenty in either sex; and, on the other hand, of the great dangers of celibacy or widowerhood after the age of manhood, or about twenty-three. He speaks of masturbation, but is hardly clear enough in his warnings as to the dangers of this very common error, or explicit enough as to what remedy he proposes for the terrible cravings of the *nisus generativus* in early manhood and womanhood.

In Chapter III. Dr. Fothergill speaks of the age of maturity, and we are glad to see that in the case of nursing mothers he acknowledges that "the use of porter and ale in order to increase the secretion of milk is of highly questionable value, and in most cases had best be avoided." Dr. Fothergill agrees with Quetelet in his opinion that the violence of the passion between the sexes seems to have considerable influence in shortening the duration of life. Hence he concludes that the marriage service should not open the way to ungoverned licence. So serious are the effects upon both sexes of excessive indulgence, he remarks that this should be pointed out. We are not quite so certain whether this common-place of British medical moralists is quite true. For one case of evil seen from excessive indulgence in married life, surely we see a hundred resulting from the abuse of alcohol or tobacco, or from celibacy and malpractices. Besides which, Dr. Fothergill must surely have found that excesses among married people are rare after the first year. Satiety and want of desire are alas! too often caused by the constant cohabitation of husband and wife. We have known of many instances where such has been the unfortunate issue of ill-assorted unions.

Chapter IV. treats of advanced life—or the period of decay, and some practical remarks are made on the sleeplessness of old age; although the prescription of a dose of alcohol at bedtime is not, we think, a good one in a work on hygiene. With regard to the superior longevity of women, we agree with Dr. Fothergill that their abstinence from alcohol is a chief cause of it. Old women are neither so fond of the bottle nor the table as old men.

Chapter V. is on food and clothes, and is a very well written *résumé* of what is known regarding human diet; we have nothing of note to say about this chapter.

Chapter VI. treats of stimulants and tobacco, and Dr. Fothergill at once admits that alcohol is a food. "It contains," he says, "no nitrogen, but it is a respiratory food. If it be not food, then neither is sugar a food, nor starch, nor any of those manifold substances employed by man which do not enter into the composition of his tissues. He who eats little and drinks alcohol in moderation retains as much in his blood and tissues as he who eats more and drinks no alcohol. In Germany it is the rule to charge the water-drinker so much more for his repast than is the tariff for the beer or wine-drinker. It is well-known that he will eat so much more."

These last sentences are enigmatical. It is clear that wines form a great portion of the profit of innkeepers; and hence they should naturally charge more for a dinner when they cannot get the silent profits which are obtained from guests drinking wine; but it is no very enticing picture of the value of beer and wine to say that they destroy the appetite of the votary. In short, alcohol is scarcely surely

a food in the sense that albumen, sugar, water, and starch are foods. We appeal to Dr. Fothergill to reflect whether the lower animals or human infants would be improved by his respiratory food. We ask him to reflect, because the unfortunate public is but too prone to accept any excuse for running to the bottle for a solace from the many sorrows of life, and doctors have, alas! sent many a person to an untimely grave by thoughtless writings of this kind. Alcoholic fluids are, like ether and chloroform, narcotics, and not at all of the nature of foods, which nourish without exciting the pulse.

Again, Dr. Fothergill says of tobacco, that, used in moderation, it exercises no injurious effect. Such kinds of observations are, to say the least of it, most unsatisfactory, and Dr. Fothergill cannot have failed to see in his life numerous instances of suffering caused by the use of tobacco. Moderation to one person is excess to another; and surely tobacco is not a food; otherwise women would be much less long-lived than men, and they do not smoke at all. Blindness, nervous prostration, and other maladies have been traced to poisoning through tobacco smoke; so that we really think it unbecoming in a writer for the outside world to take "the side of the devil" in this matter. It would seem as if some of our younger physicians were inclined to condone all evil habits, and say that everything is for the best in this best of all possible worlds. A little more sternness and a little less flattering of the *real vices* of mankind, of which drink and tobacco are surely among the chief, would seem more scientific and be vastly more useful.

The chapters which follow, on the effects of inheritance, on the election of a pursuit in life, on overwork and physiological bankruptcy, on mental strain, on hygiene, &c., are excellent, and can be read with benefit and profit by all. We have spoken freely of the chapters we disagreed with in order that the author may see that many persons will not follow him in them. We have only to add that the book is very pleasant reading, and very instructive, and we hope it will meet with a kindly reception among the public for whom it was written.

ADULTERATION OF FOOD AND DRUGS BILL.

THE Bill to repeal the Adulteration of Food Acts was brought into the House of Commons on Friday, Feb. 12, by Mr. Selater-Booth. The second reading was passed on Friday, Feb. 19.

Whereas, &c., it is

Be it therefore enacted, &c.,

1. From the commencement of this Act the 23 & 24 Vict. c. 84, 31 & 32 Vict. c. 121, s. 24, and the 35 & 36 Vict. c. 74, shall be repealed, except in regard to any appointment made under them.

2. This Act shall not apply to Scotland or Ireland except as herein provided.

Description of Offences.

4. No person shall knowingly mix, colour, stain, or powder any article of food with any ingredient or material of a nature injurious to health, with intent that the same may be sold in that state, and no person shall knowingly sell any such article so mixed, coloured, stained, or powdered, under a penalty in each case of fifty pounds for the first offence; for every subsequent offence the person shall be imprisoned for six months with hard labour.

5. No person shall knowingly, except for the purpose of compounding as hereinafter described, mix, colour, stain, or powder any drug with any other ingredient or material of a nature injurious to health, with intent that the same may be sold in that state, and no person shall knowingly sell any drug so mixed under the same penalty.

6. No person shall knowingly sell any article of food or

any drug which is not of the nature, substance, and quality of the article demanded by the purchaser, under a penalty of twenty pounds, except as herein provided; except—

Where any matter is mixed therewith for the purpose of rendering it portable, or of preserving it;

Where a harmless ingredient is mixed with it for the purpose of rendering it palatable or of improving its appearance;

Where according to the usage of trade it is sold in a mixed state;

Where it is the subject of a patent in force, and is supplied in the state required by the specification of the patent;

Where British, colonial, or foreign spirits are reduced from their ordinary strength by persons licensed and paying duties under the excise;

Where a drug is compounded either in conformity with a prescription of a registered medical practitioner or otherwise, according to the usage of trade;

Where the article is unavoidably mixed with some extraneous matter.

7. No person shall sell any article mixed for any of the purposes mentioned in the exceptions above set forth, if the matter mixed be more than is ordinarily required for the purpose, under a penalty of ten pounds.

No person shall sell any article of food which by the usage of trade is sold in a mixed state, unless the ingredients shall be mixed in the proportions required by such usage, and no person shall sell any compounded drugs, except the same shall be compounded according to the prescription in writing submitted for that purpose, or in accordance with the regulations prescribed by the British Pharmacopœia.

8. Provided that no person shall be guilty of an offence in respect of the sale of an article mixed with any ingredient not injurious to health, whether the case may or may not fall within any of the above-mentioned exceptions, if at the time of delivering such article he shall supply to the person receiving the same a notice to the effect that the article is mixed, by a label written or printed on or with the article.

9. No person shall knowingly, and with the intent that the same may be sold in its altered state without notice, abstract from an article of food any part of it so as to affect injuriously its quality, substance, or nature, and no person shall knowingly sell any article so altered without making disclosure of the alteration, under a penalty in each case of ten pounds.

Appointment and Duties of Analysts, and Proceedings to obtain Analysis.

10. Local authorities shall, for their respective city, districts, counties, or boroughs, appoint one or more persons possessing competent knowledge, skill, and experience as analysts; but such appointments and removals shall at all times be subject to the approval of the Local Government Board, who may require satisfactory proof of competency to be supplied to them, and may give their approval absolutely or with modifications as to the period of the appointment and removal, or otherwise.

12. Any purchaser of any article of food in any district, where there is any analyst, shall be entitled, on payment of a sum not more than ten shillings and sixpence, as shall be agreed upon between such person and the analyst, to have such article analysed, and to receive from him a certificate of the result.

13. Any medical officer of health, inspector of nuisances, &c., or any police constable under the direction of the local authority, may procure any sample of food or drugs, and if he suspect the same to have been sold to him contrary to any provision of this Act, shall submit the same to be analysed by the analyst of the district.

14. The person purchasing any article with the intention of submitting the same to analysis shall, after the purchase shall have been completed, notify to the seller his intention to have the same analysed by the public

analyst, and shall offer to divide the article into three parts to be then and there separated, and each part to be marked and sealed, or fastened up in such manner as its nature will permit, and shall, if required to do so, deliver one of the parts to the seller or his agent.

He shall afterwards retain one of the said parts for future comparison, and submit the third part, if he deems it right to have the article analysed, to the analyst.

16. If the analyst do not reside within two miles, such article may be forwarded to the analyst through the post office as a registered letter.

17. If any such officer shall apply to purchase any article, and shall tender the price for the quantity which he shall require for the purpose of analysis, and the person exposing the same for sale shall refuse to sell the same to such officer, such person shall be liable to a penalty of five pounds.

Proceedings against Offenders.

21. At the hearing of the information in such proceeding the production of the certificate of the analyst shall be sufficient evidence of the facts therein stated, unless the defendant shall require that the analyst shall be called as a witness.

22. The justices may, upon the request of either party, in their discretion cause any article of food or drug to be examined and analysed by the analyst of an adjoining district.

25. If the defendant in any prosecution under this Act, prove to the satisfaction of the justices or court that he sold the article in the same state as when he himself purchased it, and that he bought it, as the same article in nature, substance, and quality as that demanded of him, and with a warranty in writing to that effect, he shall be discharged from the prosecution.

26. Every penalty imposed and recovered under this Act shall be paid to the prosecutor, and shall be by such prosecutor paid to the authority for whom he acts, and be applied towards the expenses of executing this Act.

Special provision as to Tea.

30. All tea imported shall be subject to examination by persons to be appointed by the commissioners of customs for the inspection and analysis thereof, for which purpose samples may, when deemed necessary by such inspectors, be taken and with all convenient speed be examined by the analyst to be so appointed; and if upon such analysis the same shall be found to be unwholesome, mixed with other substances or exhausted tea, the same shall not be delivered unless with the sanction of the said commissioners, and on such terms and conditions as they shall see fit to direct, either for home consumption or for use as ships stores or for exportation; but if on such inspection and analysis, it shall appear that such tea is in the opinion of the analyst unfit for human food, the same shall be forfeited and destroyed or otherwise disposed of in such manner as the said commissioners may direct.

MANGOZONE; DR. MITCHELL'S PREPARED PERMANGANATE FOR INSTANTANEOUS SOLUTION.

Of all disinfectants, Condyl's fluid appears to be the one which has obtained the greatest amount of popularity. This is no doubt mainly due to the remarkable properties of the permanganate salt of which it is an aqueous solution, and the many useful applications that have been found for them by the public. Condyl's fluid has, however, a serious drawback, which prevents it coming still more into use—it is costly to purchase, being double the price of other disinfectants. This costliness has more than once been commented on by the Medical Press, and pointed out to be a mistake on the part of the makers, the late Dr. Anstie, in the *Practitioner*, having strongly urged them to diminish their prices and rely for remuneration on extended consumption rather than on an extravagant scale of profits.

What the manufacturers of Condyl's fluid did not see their

way to do has just been accomplished by the introduction of a disinfectant called by the somewhat fanciful name of Mangozone, which is stated and appears to be permanganate in a fine state of division, specially adapted for rapid solution. In the latter respect the ordinary crystallised permanganate of potash is defective, not being sufficiently soluble for extemporising a dilute disinfecting solution for immediate use. On trying the new product we have been struck with the rapid, cleanly, and even elegant manner in which a few grains thrown into water produced the beautiful pink solution with which, no doubt, all are familiar. The procedure is so simple that the wonder is it has not been brought forward long ago.

Mangozone is thus a sort of essence of Condyl's fluid, in the dry state. Besides remarkable solubility, the advantages claimed for it are—reduction of weight and bulk to 1-30th of those of disinfecting fluids in general, freedom from risk of breakage and leakage, great saving in cost of carriage, and economy in price, to the extent of 300 per cent., as compared with Condyl's Fluid. To prepare 50 gallons of dilute disinfecting solution requires, as it seems, one quart of the latter, costing four shillings, whereas a shilling tin of Mangozone gives the same result.

By those who are favourable to oxygenating disinfectants, as contra-distinguished from antiseptics, this cheap form of the best of them will be certain to be duly appreciated. We would strongly recommend its substitution for the high-priced permanganate solution now in use. Every experienced medical man must know what an important part is played by disinfectants in the treatment of many of the more serious and tedious diseases, such as the continued and exanthematous fevers, and how much high prices, among people of limited means, prevent their unrestricted use. It is hardly creditable to pharmaceutical industry that the permanganates, the manufacture of which chemistry has succeeded in cheapening so greatly, should so long have continued to be sold at prices that debar a large portion of the public from using them. We would even venture to hail as a real benefaction to suffering humanity the present attempt to render them accessible to all. It may not be out of place to state that the introduction of the new preparation is due to a medical confrère, Dr. J. B. Mitchell, who has long occupied himself with sanitary matters and practical pharmacy.

Medical News.

Royal College of Surgeons of England.—On Thursday last, at a meeting of the Council, Edward Lawford, M.D., Aberd., of Leighton Buzzard, was admitted a Fellow of the College, diploma of membership dating July 1, 1842; and Alfred George Roper, L.S.A., North End, Croydon, and Peter Broome Giles, L.S.A., Staunton-on-Wye, Hereford, were elected Fellows, their diplomas of membership bearing date respectively August 9 and December 14, 1840.

Indian Medical Service.—List of Candidates for Her Majesty's Indian Medical Service who were successful at the Competitive Examination held at Burlington House on the 15th February, 1875. Forty Candidates competed for twenty appointments. All were reported qualified.

NOTICES TO CORRESPONDENTS.

NOTICE TO SUBSCRIBERS.—The Publishers will be glad to receive the subscriptions for the past year, 1874—£1 2s. 6d. Subscriptions in advance for 1875, at the reduced tariff of 21s. per annum, post free, are now due, and also will be thankfully received by the Publishers in London, Dublin, and Edinburg.

SCARCE NUMBERS FOR 1874.—The Publisher will be glad to purchase clean copies of May 30, June 3, November 18, or to exchange any other numbers for them.

DOCTORING IN WASHINGTON TERRITORY.—A tale is told in one of our American contemporaries of the wife of an Indian chief, in Washington Territory, who lately told her noble husband that she didn't think that she should ever feel any better unless he killed her doctor. The doctor was duly killed; and upon being tried for his murder, the chief was acquitted on the ground that he acted in defence of his wife's life! This is a novel and startling view of medical matters.

MILK.—A correspondent with this signature will find Dr. Routh's work, "On Infant Feeding," fully up to his requirements.

INDIAN CORRESPONDENCE.—The letter of our Indian Correspondent arrived too late for insertion in the present number. It will appear in our next.

SANITAR.—Prof. Pettenkofer's new work referred to by us is the English translation by Dr. Hime, of Sheffield, which we understand has been revised by Dr. Pettenkofer, and may therefore be taken as the results of his latest researches. We are highly pleased with the work in every way.

DR. HARRIS.—The subject was referred to in our last and on several previous occasions: we cannot again revert to it.

THE PREJUDICE OF SAVAGES AGAINST TWINS.—Dr. Robert Brown, in his new work on "The Races of Mankind," now publishing in parts by Messrs. Cassell and Co., mentions that in Africa twins are allowed to live, but the house in which this sad freak of Nature occurs is a marked dwelling. No one, except the children and their parents, is allowed to enter the hut. The children themselves are not allowed to play with other children, and even the utensils of the hut cannot be used by any one else. The mother is not allowed to talk to any one not belonging to her own family, but is kept in the absolute seclusion consistent with the performance of her necessary household duties. If the children both survive until the end of the sixth year, it is supposed that Nature has accommodated herself to the existence of the twins; and the mother and children are released from confinement, and allowed to mingle with their species. At daybreak proclamation is made, and the mother, accompanied by a female friend, marches down the street beating a drum, and singing a song appropriate to the occasion. After which the mother and children have no restrictions thrown upon their intercourse with others. A dislike of twins is a widespread superstition. In the Island of Bali, near Java, a woman who is unfortunate enough to have twins is obliged, along with her husband, to betake herself to the sea-shore or the tombs, and there for the space of a month to live, until she gets purified, and, after making a suitable sacrifice, can return to the village. The Khasias of Hindostan consider that to have twins assimilates the mother to the lower animals, and accordingly one of them is frequently killed. An exactly similar custom, coupled with the same idea regarding the disgrace of having twins, prevails among some of the Vancouver Island tribes. Among the Ainoo—aborigines of the islands north of Japan—one of twins is always killed; but in Arebo, in Guinea, both they and the mother are killed. The same idea prevails among various other barbarian or savage tribes.

MEETINGS OF THE LONDON SOCIETIES.

Wednesday, March 3rd.—Royal College of Surgeons, 4 p.m. Prof. W. K. Parker, "On the Structure and Development of the Skull."

ROYAL COLLEGE OF PHYSICIANS.—5 p.m. Dr. Greenhow, "On Addison's Disease."

ANATOMICAL SOCIETY.—8 p.m. Dr. Oswald, "Notes of a Case of Suppurating Tumour of the Left Ovary" with Specimen. Dr. Lieberman (of Trieste), "Clinical Notes on the Early Course of Cancer of the Cervix Uteri." Dr. Savory, "On a Case of Epithelioma of the Cervix Uteri complicated with Pregnancy; removal of Diseased Portion; subsequent Delivery of a Healthy Child; recurring Pregnancy." Dr. G. ... "On Prolapse of the Funis during Labour." And other communications.

Thursday, March 5th.—Royal College of Surgeons, 4 p.m. Prof. W. K. Parker, "On the Structure and Development of the Skull."

ROYAL COLLEGE OF PHYSICIANS, 5 p.m. Dr. Greenhow, "On Addison's Disease."

ROYAL INSTITUTION.—8 p.m. Weekly Evening Meeting. 9 p.m. Lord Rayleigh, "On the Dissipation of Energy."

MEDICAL SOCIETY.—8 p.m. Monthly Council Meeting.

SATURDAY, March 6th.—Royal Institution, 3 p.m. Prof. W. K. Clifford, "On the General Features of the History of Science."

MONDAY, March 8th.—Medical Society, 8 p.m. Anniversary.

TUESDAY, March 9th.—Royal Medico-Chirurgical, 8½ p.m. Ordinary Meeting.

VACANCIES.

Coventry Hospital. House Surgeon. Salary, £100, with board and residence. Applications to the Secretary.

Chorley Union. Medical Officer of Health. Salary, £150 per annum. Full particulars of the Secretary.

Dorset County Hospital. House Surgeon and Secretary. Salary, £80, with board and residence. Applications, under cover, to the Chairman.

St. Bartholomew's Hospital. Two Casualty Physicians. Applications to be left at the Clerk's Office.

Clinical Hospital for Children, Manchester. House Surgeon. Salary, £80, with board and residence. Address the Chairman of the Medical Board.

University College. Curator of the Museum of Anatomy. Salary, £200 per annum. Testimonials to be sent to Mr. Robson, B.A., at the College, Gower Street, London.

St. Thomas's Hospital. Assistant Obstetric Physician. Applications, with testimonials, to be sent to the Treasurer, at the Hospital.

Bradford Infirmary. Physician. Diplomas, &c., to be sent to the Secretary, 63 Market Street, Bradford.

Newmarket Union. Medical Officer. Salary, £45, exclusive of fees. Forms of application may be obtained of the Clerk to the Guardians.

Southport Infirmary. House Surgeon. Salary, £100, with board. Applications to the Secretary, endorsed "House Surgeon."

Leominster Union. Medical Officer. Salary, £90, with fees extra. Apply to the Clerk to the Guardians.

APPOINTMENTS.

BALLENDEY, JOHN M'NAB, M.D., St. And., L.F.P.S. Glasg., Medical Officer of Health for the Upper Sedgeley Urban Sanitary District.

BARRETT, C., F.R.C.S.E., Medical Officer and Public Vaccinator for the Shrivenshead District of the Farringdon Union.

CHEESEWRIGHT, J. F., M.R.C.S.E., L.R.C.P. Ed., Medical Officer of Health for Greasbrough, Yorkshire.

DRAPER, M. R., L.S.A. L., Medical Officer to the Redditch and District Medical Association.

GRIFFITHS, J., M.R.C.S.E., a Junior House Surgeon to the Royal Free Hospital, London.

HALLOWES, A. H. B., M.R.C.S.E., a Surgeon to the West Kent General Hospital, Maidstone.

HEWAT, P. G., F.R.C.S.E., a Consulting Surgeon to St. George's Hospital, on resigning as Surgeon.

JEFFERIES, W. R. S., M.D., C.M., Medical Officer and Public Vaccinator for the Parish of Lochaben, Dumfriesshire.

LAWRENCE, A. E. A., M.D., Physician-Accoucheur to the Bristol General Hospital.

MACAULAY, J. C., M.R.C.S.E., Medical Officer for No. 3A District of the Hinton Union, Devon.

M'BRIDE, C., M.D., Medical Officer (*pro tem.*) to the County Prison, Wigtown.

M'GREGOR, J., M.B., C.M., Medical Officer and Public Vaccinator for the Parish of Morven, Argyleshire.

PARSONS, F. J., L.R.C.P. Ed., M.R.C.S.E., L.M., Medical Officer of Health for the Portland Park Sanitary District.

PINK, T., F.R.C.S., a Junior House Surgeon to the Royal Free Hospital, London.

ROBERTS-LUDLEY, F. J., M.R.C.S.E., Medical Officer for No. 3 District of the Ashton-under-Lyne Union.

ROUSE, J., F.R.C.S.E., a Surgeon to St. George's Hospital.

SHACKELFORD, S., M.R.C.S.E., Medical Officer and Public Vaccinator for No. 3 District of the Market-Harborough Union, Leicestershire.

SMITH, J. G., L.R.C.S. Ed., Certifying Factory Surgeon for Thurso.

SWAYNE, J. G., M.D., Consulting Physician-Accoucheur to the Bristol General Hospital.

SPENSER, L. W., L.R.C.P. Ed., M.R.C.S.E., Medical Officer of Health for the Preston Rural Sanitary District.

WIMPENY, J., M.R.C.S.E., Medical Officer of Health for the Astonley, Cartworth, Fulstone, Hepworth, Holme, Honley, Netherthong, Scholes, Uppethong, and Woldale Urban Sanitary Districts.

Deaths.

CARROLL.—On the 10th Feb., at Trim, co. Meath, Raymond Harvey Carroll, Staff Surgeon R.N., aged 46.

COLLISON.—On the 29th Feb., at Sandgate, A. C. Collinson, M.R.C.S., aged 25.

CRABB.—On the 17th Feb., Alfred Crabb, M.D., of Poole, aged 61.

HALLEY.—On the 25th Feb., at his residence, 16 Harley Street, London, Alexander Halley, M.D., F.G.S., aged 61.

HUGHES.—On the 13th Feb., at Rothersey House, Pittville, Cheltenham, David Hughes, Surgeon, late of Rainhill, and formerly of Liangollen, aged 62.

MARTIN.—On the 10th Feb., at Cambridge Street, Edinburgh, James Martin, M.D., of Leadhills, Lanarkshire, late of the 6th Fusiliers, aged 55.

SWAIN.—On the 23rd Feb., at Brindley Ford, Congleton, J. H. Swain, M.D., aged 36.

TUCKEY.—On the 18th Feb., at Bantry, co. Cork, Abraham John Tuckey, M.D., M.R.C.S.

THOMSON.—On the 17th Feb., at Kew Terrace, Glasgow, Robert Thomson, Surgeon.

WOOLMER.—On the 21st Feb., Joseph Benson Woolmer, M.R.C.S.E., of Warwick Square, Fimlico.

SURGICAL INSTRUMENTS FOR SALE.—A full Case of Surgical Instruments, by Weiss and Co. London, never used. Also FOR SALE, the several Volumes and Plates of the OLD and NEW SYDENHAM SOCIETY.—Apply to R. S., 23 Ely Place, Dublin.

TO INVALIDS AND OTHERS.—TO LET, in the House of a married Medical Gentleman without children, TWO NICE ROOMS, furnished, overlooking a superb Park. Attendance and medical care if required. Any communications, no matter of what nature, will be confidentially answered.—Address PHYSICIAN, Post-Office, Broadway, Deptford, S.E.

SURGICAL SOCIETY OF IRELAND.—The NEXT MEETING of the SOCIETY will take place on FRIDAY EVENING, 6th MARCH, 1875. Chair will be taken at half-past eight o'clock precisely. B. WILLS RICHARDSON, F.R.C.S.I., } Hon. Secs.
HUMPHREY MINCHIN, F.R.C.S.I., }
Royal College of Surgeons, Dublin,
3rd day of March, 1875.

SOCIETY for RELIEF of WIDOWS and ORPHANS of MEDICAL MEN.—Founded 1788.—Incorporated by Royal Charter 1864.—The MEMBERS are reminded that a QUARTERLY COURT of DIRECTORS will be held on the 14th of APRIL, 1875. Candidates for admission into the Society desirous of being balloted for at the Meetings must send their forms of proposal to the Secretary on or before March 23rd. The forms of proposal may be obtained of the Secretary. The benefits of the Society are restituted to the families of deceased Members of not less than two years' standing. The Secretary attends at the office every Wednesday and Friday, from 4 to 5 o'clock.

J. B. BLACKETT, Secretary.

53 Berners Street, W., March 2nd, 1875.

LECTURES ON HOMOEOPATHY, instituted by the British Homoeopathic Society.—Course of Lectures on MATERIA MEDICA by Dr. RICHARD HUGHES.—The next Lecture will be delivered at the London Homoeopathic Hospital, Great Ormond Street, Russell Square, W.C., on Thursday next, March 4th, at 5 p.m. Subject: ACIDUM NITRICUM, PHOSPHORICUM SULFURICUM; and on ACONITUM.

Members of the Medical Profession will be admitted on presentation of their address cards. Medical Students can obtain admission on application to Dr. Bayes (Hon. Sec. to Lectures Committee), 28 Brook Street, W.

LOCUM TENENS.—A trebly-qualified Gentleman, in his twenty-eighth year (son of a Clergyman), wants an engagement as above. Has acted as such before, and has held a Union Appointment. An Assistency with ultimate succession preferred if in Ireland.—State particulars to A. M., office of this paper, 23 Ely Place, Dublin.

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

PATRON:—H.R.H. THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £25 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of five Guineas gives the donor a life-vote. Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c. can be had at the office,

40 MOLESWORTH STREET, DUBLIN,
W. O'NEILL, Secretary.

M^r. I. SANDHEIM,

Dentist,

16 SUFFOLK STREET,

DUBLIN.

N.B. — A Vacancy for a Pupil.

BUTLER'S MEDICAL HALL,

53 & 54 LOWER SACKVILLE STREET,
DUBLIN.

ESTABLISHED A.D. 1817,

For Compounding Prescriptions and Supplying Genuine Medicines, &c. conducted, as formerly, under the careful superintendence of

WILLIAM STARKLY, M.D.,
Licentiate Apothecary

Established 1848.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S.,
&c. (Kirk's Coll.), and Author of VIA MEDICA.

Has always upon his books a large number of desirable Investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

PRACTICES AND PARTNERSHIPS NOW OPEN for Negotiation (in addition to those advertised in Dr. Langley's List, which is sent post free on application).

Z 120. BRANCH PRACTICE, wholly transferable. Present receipts £250 a year, with scope for increase to £600. Population 4000. No opposition. Co-operation of the Principal as long as desired. Easy terms.

Z 119. SOUTH WALES. Small PRACTICE for Sale. Actual receipts, £350 a year. Appointments, £108. District agricultural. All expenses small. Considerable scope for increase.

Z 118. DEATH VACANCY. Unopposed PRACTICE in a pleasant country town, within 60 miles of Town. Receipts about £600 a year, with good appointments, but could be increased to £1000, at which they originally stood before the illness of the late Incumbent. Patients good class. An efficient introduction can be given.

Z 117. On the SOUTH COAST, an OPEN SURGERY and RETAIL for sale. Prescribing business yields about £350 a year, but the income could be doubled by Outdoor Practice, which has been declined. Premium, £300.

Z 121. FAMILY PRACTICE in a small Midland town. Receipts upwards of £1000 a year. Appointments, £155. The residence is large and convenient, with stabling, paddocks, garden, &c. The Incumbent retires in consequence of ill-health, but a good introduction can be given.

Z 116. Within fifty miles of London. A TRANSFERABLE PRACTICE, yielding upwards of £460 a year. The Incumbent retires in consequence of advancing age, but can give an introduction as long as desired. An active gentleman would make £600 a year. Appointments produce £230 a year. The work is light. The house contains ten rooms, and can be taken with or without land. Midwifery fees, £1 ls. and upwards. No opposition within four miles.

Z 115. In the suburbs of a large town, where there is unlimited scope for increase, a good GENERAL PRACTICE for transfer. Receipts, £500 a year. Appointments, £200. One horse does the work. Partnership introduction if desired.

Z 110. In a wealthy suburb of a large town, a good FAMILY PRACTICE, yielding £600 a year. The locality is rapidly improving, and the residents are of the best class. Midwifery £1 ls. and upwards. Good modern house, with stabling, &c. Rent £60. A very efficient introduction would be given, and the whole connection could be transferred to a suitable gentleman. The scope for increase is undeniable.

Z 103. YORKSHIRE, in a large town. Excellent NUCLEUS, producing £450 a year, and affording a good introduction to a very large practice. Pleasant house, with garden, &c. Rent £35. Premium £350, part of which may be left on security.

THE CANTOR LECTURES AT THE SOCIETY OF ARTS FOR 1875.

ON ALCOHOL

By B. W. RICHARDSON, M.D., F.R.S.

[These lectures, endowed originally by Dr. Cantor, are delivered annually at the Society of Arts. This year Dr. Richardson was the lecturer, his subject Alcohol. He treated it as fully as possible in a course of six lectures. The first was confined to the history of the subject, and the second to its chemistry. In the third lecture the primary physiological action of alcohol was considered. In the fourth Dr. Richardson discussed the question "Is alcohol food?" To this he replied with a decided negative. The fifth lecture detailed the secondary physiological action of alcohol, and entered on a consideration of the injury to tissues caused by excessive use of that substance. The sixth followed up the last point, and entered on others strictly medical. This last will be found so interesting that we have much pleasure in printing it almost entire.]

The parts which suffer most, at first, from alcohol, are those expansions in the animal body which the anatomists call the membranes. The membranes are colloidal structures, and every organ is enveloped in them. The skin is a membranous envelope; through the whole of the alimentary surface, from the lips downwards, and through the bronchial passages to their minutest ramifications, extends the mucous membrane; the lungs, the heart, the liver, the kidney, are folded in delicate membranes, which you can strip easily from these parts. If you take a portion of bone you will find it easy to strip off from it a membranous sheath or covering; if you open and examine a joint you

will find both the head and the socket lined with membrane.

The whole of the intestines are enveloped in fine membrane, called peritoneum. All the muscles are enveloped in membranes, and the fasciculi or bundles and fibres of muscles, have their sheathing. The brain and spinal cord are enveloped in these membranes; one nearest to themselves, a pure vascular structure, a network of blood-vessels; another, a thin serous structure; a third, a strong fibrous structure. The eyeball is a membrane of colloidal humours and membranes, and of nothing else. To complete the construction, the minute structures of the vital organs are enrolled in membranous matter.

It was held by the old anatomists that this membranous arrangement of the body is mainly mechanical. The parts and organs, according to their view, are supported and held in position by these membranous sheaths and pouches and coverings. Doubtless this is a portion of their usefulness, for in fact they do hold all the structures together in the most perfect order. But this is only a small part of their duties. The membranes are the filters of the body. In their absence there could be no building of structure, no solidification of tissue, no organic mechanism. Passive themselves, they nevertheless separate all structures into their respective positions and adaptations.

The animal receives from the vegetable world and from the earth the food and drink it requires for its sustenance and motion. It receives colloidal food for its muscles; combustible food for its motion; water for the solution of its various parts; and salts for constructive and other physical purposes. They have all to be arranged in the body, and they are arranged by means of the membranous envelopes. Through these membranes nothing can pass that is not for the time in a state of aqueous solution like to water or soluble salt. Water passes freely through them, salt passes freely through them, but the constructive matter of the active parts that is colloidal does not pass; it is retained in them until it is chemically decomposed into the soluble type of matter. When we take for our food a portion of animal flesh, it is first resolved in digestion into a soluble fluid before it can be absorbed; in the blood it is resolved into the fluid colloidal condition; in

the solids it is laid down within the membranes into new structure, and when it has played its part it is digested again, if I may so say, into a crystalloidal soluble substance ready to be carried away and replaced by addition of new matter, then it is dialysed or passed through the membranes into the blood, and is disposed of in the secretions.

See, then, what an all-important part these membranous structures play in the animal life. Upon their integrity all the silent work of the building up of the body progresses. If these membranes are rendered too porous, and let out the colloidal fluids of the blood—the albumen for example—the body so circumstanced dies; dies as if it were slowly bled to death. If, on the contrary, they become condensed and thickened, or loaded with foreign material, then they fail to allow the natural fluids to pass through them. They fail to dialyse, and the result is either an accumulation of the fluid in a circumscribed cavity or contraction of the substance enclosed within the membrane, or a dryness of membrane in surfaces that ought to be freely lubricated and kept apart. In old age we see the effects of modification of membrane naturally induced; we see the fixed joint, the shrunken and feeble muscle, the dimmed eye, the deaf ear, the enfeebled nervous function.

It may possibly seem to some of you, at first sight, that I am leading away from the subject of the secondary action of alcohol. Not so. I am leading directly to it. Upon all these membranous structures alcohol exerts a direct perverting power of action. It produces in them a thickening, a shrinking, and an inactivity that reduces their functional power. That they may work rapidly and equally they require to be at all times charged with water to saturation. If into contact with them any agent is brought that deprives them of water, then is their work interfered with; they cease to separate the saline constituents properly, and if the evil that is thus started be allowed to continue, they contract upon their contained matter in whatever organ it may be situated, and condense it.

In brief, under the prolonged influence of alcohol those changes which take place from it in the blood-corpuscles, and which have already been described, extend to the other organic parts, involving them in structural deteriorations, which are always dangerous, and which are often ultimately fatal.

Preliminary effects on the vital functions.—I remarked at last lecture that the slow or chronic effects of alcoholic drink upon the body was to induce a series of stages analogous in all respects, except in period of duration, to the process of acute poisoning by the same agent. In the first prolonged stage there occur phenomena of disease which are as characteristic of the agency when it is known as they are deceptive when the agency is not known.

The ultimate changes that follow the use of alcohol by those who indulge in it, in what is too often considered a temperate degree, are actual local changes within one or other of the vital organs. But before such actual deterioration obtains, there are usually other phenomena, transitory in character, yet unequivocal. I pointed out certain of these at the last lecture, but I did not specify them all.

In addition to that irritation of mind and suffering, "of wounds without cause," to which I then drew attention, an extreme emotional derangement is often produced. The afflicted man—and I fear I must say woman also, for women are sometimes afflicted—the afflicted man, under this primary prolonged influence of alcohol, becomes nervous and excitable, ready at any moment to cry or to laugh, without valid reasons for either act. The emotional centres are alternately raised and depressed in function by the poison, but after a time the depression overcomes the exhilaration, and the impulse is to a maudlin sentimentality extending even to tears. The slightest anxieties are then exaggerated, and there is experienced at the same time an indecision and deficiency of self-confidence which is doubly perplexing. When an act is done, when a letter, for instance, or other piece of business has been

finished and despatched, an uneasy feeling of distrust is felt that perhaps some mistake has been made, which distrust passes rapidly into a sentiment that the thing cannot be helped; it is bad luck, but it must take its chance. In various other directions this distrust shows itself, and the worst of all is that the very doubt prompts the desire for another application for relief to the evil that is the cause of the burthen. A small drachm more of the stimulant, not an overpowering draught that will cause quick and sure insensibility, but just a mouthful, that is the remedy, and that is the certain promoter of the sorrow.

We know now as surely as if we could see within the body, what is the condition of the organs of the person afflicted in the manner thus defined. We are conscious that the vessels of the brain, of the lungs, of the liver, of the kidneys, of the stomach, are paralysed, and are injected to full distension with blood. Some of these parts have actually been seen under this state, and the fact of the red injected condition directly demonstrated.

Alcoholic dyspepsia.—Of all the systems of organs that suffer under this sustained excitement and paralysis, two are injured most determinately, viz, the digestive and the nervous. The stomach, unable to produce in proper quantity the natural digestive fluid, and also unable to absorb the food which it may imperfectly digest, is in constant anxiety and irritation. It is oppressed with the sense of nausea; it is oppressed with the sense of emptiness and prostration; it is oppressed with a sense of distension; it is oppressed with a loathing for food; and it is teased with a craving for more drink. Thus there is engendered a permanent disorder, which, for politeness' sake, is called a dyspepsia, and for which different remedies are often sought, but never found. Antibilious pills—whatever they may mean—Seidlitz powders, effervescing waters, and all that pharmacopoeia of aids to further indigestion in which the afflicted who nurse their own diseases so liberally and innocently indulge, are tried in vain. I do not strain a syllable when I state that the worst forms of confirmed indigestion originate in the practice that is here explained. By this practice all the functions are vitiated, the skin at one moment is flushed and perspiring, at the next is pale, cold, and clammy, and every other secreting structure is equally decomposed.

Nervous derangements.—The nervous structures follow the stomach in the order of derangement, or it may be precede it. We have not yet traced out with sufficient care the conditions of the centres of the organic chain of nerves, but we know that they are reduced in power; and, in regard to those higher and reasoning centres, the brain and its subsidiary parts, the spinal cord and voluntary nerves, we are aware that they are supplied with blood through vessels weakened, and in a condition either of undue tension or undue relaxation. Moreover, the delicate membrane which envelopes and immediately surrounds the nervous cords is acted upon more readily by the alcohol than the coarser membranous textures of other parts, and thus a combined arrangement of evils affects the nervous matter. The perverted condition of the nervous centres gives rise to many striking phenomena, extending from them to the nervous cords and to the organs of sense. The irregular supply of blood to the retina causes temporary disturbances of vision, with appearances before the eyes of those specks and small rounded semi-transparent discs, which are called by the learned *musca volitantes*. From the imperfect tension of the arteries, the blood which rushes through causes dilatation of them, and in the bony canals of the skull an impingement is made upon the bony structure. Vibrations which extend to the neighbouring organ of hearing are thus produced, giving rise to sounds of a murmuring, ringing, or humming character, according to the modification of the arterial tension.

The perverted condition of the membranous covering of the nerves gives rise to pressure within the sheath of the nerve, and to pain as a consequence. To the pain thus excited the term neuralgia is commonly applied, or tic; or if the large nerve running down the thigh be the

seat of the pain, "sciatica." Sometimes this pain is developed as a toothache. It is pain in nearly every instance, commencing at some point where a nerve is enclosed in bony cavity, or where pressure is easily excited, as the lower jawbone, near the centre of the chin, or at about the opening in front of the lower part of the ear, or at the opening over the eyeball, in the frontal bone.

Alcoholic insomnia, or sleeplessness.—Lastly, on this head the perverted state of the vessels of the brain itself, the unnatural tension to which they are subjected from the stroke of the heart, which they are so incompetent to resist, sets up in the end one telling, and of all I have yet named the most serious phenomenon, I mean *insomnia*, inability to partake of natural sleep. There is a theory held by some physiologists that sleep is induced by the natural contraction of the minute vessels of the brain, and by the extrusion, through that contraction, of the blood from the brain. I am myself inclined, from reasons I need not wait to specify now, to consider this theory incorrect; but it is nevertheless true that during natural sleep the brain is receiving a reduced supply of blood; that when the vessels are filled with blood without extreme distension the brain remains awake, and that when the vessels are engorged and over distended there is induced an insensibility which is not natural sleep, but which partakes rather of an apoplexy. This sleep is attended with long and embarrassed breathing, blowing expirations, deep snoring inspirations, and uneasy movements of the body, with even convulsive motion, from which the apparent sleeper wakes unrefreshed and unready for the labours of the day. The effect of alcohol, then, on the brain is to maintain the relaxation of vessel, to keep the brain charged with blood, and so to hold back the natural repose. Under such form of divergence from the natural life, the sleepless man lies struggling with unruly and unconnected trains of thought. He tries to force sleep by suppressing with a great effort all thought, but in an instant wakes again. At last the more he tries the less he succeeds, until the morning dawns. By that long time the spirit that kept his cerebral vessels disabled and his heart in wild unrest, having become eliminated, he is set free, and the coveted sleep follows. Or perhaps wearied of waiting for the normal results, he rises, and with an additional dose of the great disturber, or with some other tempting narcotic drug of kindred nature, such as chloral, he so intensifies the vascular paralysis, as to plunge himself into the oblivion of congestion, with those attendant apoplectic phenomena, which he himself hears not, but which, to those who do hear, are alarming in what they forbode, when their full meaning is appreciated. Connected with this sleep there is engendered in some persons a form of true epilepsy, which all the skill of physic is hopeless to cure, until the cause is revealed and removed.

And now I think I have said everything that I have time to say respecting the general phenomena incident to this primary stage of slow alcoholic intoxication in those who in the world's eye, as well as in their own, are temperate individuals—individuals who enjoy the choice things of this life heartily; who understand a glass of wine, and who can take a good many glasses, or a good many little goes of spirit if that be all, but who are never known by friend or foe to be worse for anything they take; who grow mellow as an apple under the mellowing cheer, but never fall, nor lose their power of taking less guarded companions safely home.

Organic deteriorations.—The continuance of the effects of alcohol into a more advanced stage leads to direct disorganisation of vital structures. When once this stage has been reached not one organ of the body escapes the ravage. According to the build or the hereditary construction of the individual, however, or according sometimes to what may be considered a local accident, some particular organ undergoes a change which gives a specific character to the whole of the phenomena that are afterwards presented. We then say of the person in whom such change occurs that he is afflicted with such a particular disease, letting the general sink into the local manifes-

tation. Many purely local modifications of structures and parts are in this manner induced in the blood; in the minute structure of the moving organs—the muscles; in the fixed vital organs, such as the brain, the lungs, the liver, the heart, the kidney. In the blood the influence is exerted upon the plastic fibrine and upon the corpuscles; in the brain, on the membranes at first, and afterwards on the nervous matter they enclose; in the lungs, on the elastic, spongy, connective tissue, which is, strictly speaking, also membranous; in the heart, on its muscular elements and membranes; in the liver primarily on its membranes; in the kidney, on its connective tissue, tubules, and membranes.

Special structural deteriorations.—The organ of the body that perhaps the most frequently undergoes structural changes from alcohol is the *liver*. The capacity of this organ for holding active substances in its cellular parts is one of its marked physiological distinctions. In instances of poisoning by arsenic, antimony, strychnine, and other poisonous compounds, we turn to the liver in conducting our analysis, as if it were the central depot of the foreign matter. It is, practically, the same in alcohol. The liver of the confirmed alcoholic is probably never free from the influence of the poison; it is too often saturated with it.

The effect of the alcohol upon the liver is upon the minute membranes or capsular structure of the organ upon which it acts to prevent the proper dialysis and free secretion. The organ at first becomes large from the distension of its vessels, the surcharge of fluid matter and the thickening of tissue. After a time there follows contraction of membrane, and slow shrinking of the whole mass of the organ in its cellular parts. Then the shrunken, hardened, roughened mass is said to be "hob-nailed"—a common but expressive term. By the time this change occurs the body of him in whom it is developed is usually dropsical in its lower parts, owing to the obstruction offered to the returning blood by the veins, and his fate is sealed.

Now and then, in the progress to this extreme change and deterioration of tissue, there are intermediate changes. From the blood, rendered preternaturally fluid by the alcohol, there may transude, through the investing membrane, plastic matter which may remain interfering with natural function, if not creating active mischief. Again, under an increase of fatty substance in the body, the structure of the liver may be charged with fatty cells, and undergo what is technically designated fatty degeneration. I touch with the lightest hand upon these deteriorations, and I omit many others. My object is gained if I but impress you with the serious nature of the changes that, in this one organ alone, follow an excessive use of alcohol.

In the course of the early stages of deterioration of function of the liver from organic change of structure, another phenomenon leading speedily to a fatal termination is sometimes induced. This new malady is called diabetes, and consists in the formation in enormous quantity within the body of glucose, or grape-sugar, which substance has to be eliminated by dialysis, through the kidney—a fatal elimination. The injury causing this disease through the action of alcohol may possibly be traced back to an infliction upon the nervous matter; but the appearance of the phenomenon is coincident with the derangement of the liver, and I therefore refer to it in this place.

The *kidney*, in like manner with the liver, suffers deterioration of structure from the continued influence of alcoholic spirits. Its minute structure undergoes fatty modifications; its vessels lose their due elasticity and power of contraction; or its membranes permit to pass through them that colloidal part of the blood which is known as albumen. This condition reached, the body loses in power as if it were being gradually drained even of its blood. For this colloidal albumen is the primitively dissolved fluid out of which all the other tissues are by dialytical processes to be elaborated. In its natural

destination it has to pass into and constitute every colloidal part.

The *lungs* do not escape the evil influence that follows the persistent use of alcohol. They, indeed, probably suffer more than we at present know from the acute evils imposed by this agent. The vessels of the lungs are easily relaxed by alcohol; and as they, of all parts, are most exposed to vicissitudes of heat and cold, they are readily congested when, paralysed by the spirit, they are subjected to the effects of a sudden fall of atmospheric temperature. Thus the suddenly fatal congestions of lungs which so readily befall the confirmed alcoholic during severe winter seasons.

(To be continued.)

ON THE ANTECEDENTS AND TREATMENT OF TERTIARY SYPHILIS. (a)

By C. R. DRYSDALE, M.D., M.R.C.P. Lond., F.R.C.S.E.,
Senior Physician to the Metropolitan Free Hospital.

ACCORDING to Dr. Fournier, mercury, in general, cures syphilis, but not always, any more than quinine always cures ague. He scarcely ever uses corrosive sublimate, which is greatly disliked at the Lourcine Hospital by the female patients, who style the drug *casse poitrine*. It is curious that I hear that perchloride of mercury is not given out by the heads of the Naval Department for use by the medical officers in the United Kingdom.

I have already said that I have become a convert to the use of mercury chiefly by these arguments of Dr. Fournier and by conversations with him, as also by Mr. Hutchinson's papers of 1874. My own prolonged experience of the treatment of syphilis without mercury soon led me to see clearly two or three points. First of all, I learnt that tertiary symptoms may arise quite without any mercury. This is now so well made out that I think it may be said to be believed by almost every practitioner in Europe, with the exception, perhaps, of Dr. Hernmann, of Vienna. But I also learnt before I abandoned mercury that persons treated carelessly by salivation and over-doses of mercury had sometimes extremely severe tertiary symptoms.

One gentleman, in 1863, came to me with innumerable cicatrices over all parts of his body, caused by tertiary syphilis. He had taken long and severe courses of mercury for many, many years during his unfortunate career. A poor woman, who has haunted me for many years past, with one of the worst tertiary throats I have ever seen, had been frequently and severely salivated about the year 1860. Time after time was she cured by large doses of iodide of potassium, and I attributed the gravity of her case mainly to the salivations she formerly underwent.

I have, furthermore, seen a great number of cases of secondary syphilis treated by doses of the iodide of potassium get quite well, and no tertiaries arrive after ten or eleven years. Thus, an elderly gentleman consulted me in 1863 for syphilitic roseola and mucous patches, and was treated with iodide of potassium, and quite without mercury. The result was, that he remained quite well until 1873, when he again called on me, this time affected with a totally different disease—gonorrhœa, which, being in what Dr. Bertillon has so well shown to be the dangerous condition of widowerhood, he had contracted at the age of sixty-seven. He had had no more secondary symptoms since 1863, and not the slightest tertiary. Such cases are common enough in treatment without mercury. I have had many cases which might well justify the saying of Dr. Lancereaux, that "clinical syphilis is a mild disease." Yet, on listening to the lecture of my friend Dr. Fournier in 1871, I

could not help feeling that, as he put it, this was a matter of counting; and, as I had found syphilitic sarcocele, tertiary sore-throat, ozena, and ulcers of the skin, occur frequently enough in my own non-mercurial treatment, I resolved to give the mercurial treatment a fair trial, and see whether it would prevent the dreaded tertiary stage.

I now come to the second point, and that is, the *Treatment of Tertiary Syphilis*.

Will it be believed? There has of late arisen quite an outcry against the value of iodide of potassium in the treatment of tertiary syphilis! Now, I should at once like to lay it down as a rule of practice, that, in this phase of syphilis, iodide of potassium is the remedy. Tertiary accidents, I may remark, may occur under all methods of treatment, and our patients should be informed of this, since it may be of the greatest importance for them to know it, when in ten, twenty, thirty, or forty years they may perchance be struck with some obscure symptom, possibly caused by syphilis. Tertiary accidents are continually misunderstood, and the great remedy for them is iodide of potassium.

There are, it is true, certain lesions which may be ranged either in the late secondary, or in the early tertiary period, such as rupia, sarcocele, and ecthyma, and in these cases mercury is alleged by Mr. Hutchinson occasionally to be of signal service; but these accidents may be called secundo-tertiaries. True tertiary syphilis rarely occurs before the second year; but after that may arise at any subsequent period of the patient's life. Patients usually seem in perfect health when the tertiary lesion appears. Tertiary lesions come on insidiously, and are often quite silent in evolving themselves, so much so that perforation of the soft palate often occurs quite suddenly, without the patient having paid much attention to the disease, which has been going on quietly for some time.

Tertiary syphilis attacks the parenchyma of the tissues. The whole body is its domain, and belongs to it from head to foot. Its two pathological characteristics are gummy products and hardening of the tissues. Syphilis, as it grows older, loses its aspect as a venereal affection, and, as M. Ricord quaintly expresses himself, "it has an honest look;" so much so that, under certain surroundings, the practitioner scarcely dares venture to suspect the existence of the disease. In such cases it is that the old adage is of service, "In dubio, suspice Venerem."

Tertiary syphilis is always a grave disease, and is frequently the cause of death, far more frequently, I think, than is generally supposed. Fortunately, it obeys therapeutic remedies far more readily than primary or secondary lesions do, and iodide of potassium is the remedy *par excellence* of this stage. Indeed, that drug enjoys such curative powers in the vast majority of cases that it is quite a marvellous and incomparable remedy. Some day or other, perhaps, the citizens of Dublin may be induced to erect a statue to Wallace, the discoverer of this priceless boon to syphilitic patients.

Now, before I advert to the other side of the case, let me just remind persons of experience of the lesions in which proper doses of iodide of potassium act so splendidly. First of all, then, in all cases of periostitis and nodes, whether in the long bones, on the skull or face, it is the only truly efficient remedy, and is most rapid in its action. Then, again, in ozena, large doses of the iodide of potassium very often cure the disease in a week or two. In that dangerous lesion of the throat dependent on old syphilis the wary practitioner will shun all paltering with mercury, and at once, without a moment's delay, pour in large quantities of iodide of potassium, thus saving his patient's powers of deglutition and phonation. To give mercury in such cases is, in my experience, a grave error in practice. In sarcocele, too, the iodide of potassium rapidly melts down the gummy deposits, leaving the testis free.

However, let it be remembered, that the iodide of potassium, even aided by mercury, in obstinate cases, is not all-powerful or infallible against tertiary symptoms. Like other great remedies of our Pharmacopœia, it has its failures and reverses. From one cause or another, tertiary lesions

(a) A paper read at the Medical Society of London on the 15th February, 1875, Mr. Victor de Meric, President of the Society, in the chair.

may become unamenable to any treatment, whether it be that the remedy have arrived too late, or common inflammation exists around the syphilitic lesion, such as is found in syphilis of the brain. Certain cases seem beyond the reach of art, especially in the case of diseases of the nervous system. Palsies of syphilitic origin are but too often incurable. There are, too, cases where grave relapses take place, where we are always curing the patient without ever effecting a complete cure—desperate cases of syphilis, where the life of the patient is one long tragedy.

It has been said lately by an author of experience in this country that, putting aside cases of injury, hemiplegia and paraplegia occurring in a person between the ages of twenty and forty, not associated with albuminuria and embolism, are in nineteen cases out of twenty the results of syphilis (Buzzard on "Syphilitic Nervous Affections"). Hence the importance of trying iodide of potassium and even mercury in all cases of palsy occurring insidiously among young adults.

I have said that, of late years, there has been quite a wide-spread tendency, especially in Germany, headed by Dr. Virchow, to detract from the fame of the iodide of potassium in the treatment of tertiary syphilis, and to put forward mercury as the grand treatment for syphilis in all its periods. That very thoughtful and distinguished practitioner, Dr. Hardy, of Paris, for instance, in his work "Sur les Maladies de la Peau," p. 208, admits that tertiary symptoms are pretty rapidly ameliorated by iodide of potassium, and that this drug is used by all practitioners; but, whereas the majority prescribe it alone, he thinks it preferable to administer mercury with it, and, therefore, orders one or two mercurial pills at night, and fifteen to twenty grains of iodide of potassium in the day, in the majority of cases of deep syphilitic ulcerations that he sees. In a lecture delivered last year by my friend, Mr. Balmanno Squire, I could observe the same idea, as to the unsufficiency of the iodide of potassium, pervading all that was said as to the treatment of tertiary lesions.

Aix-la-Chapelle has lately gained quite a renown for the treatment of syphilis, and there again I find the most popular practitioners speaking, as I think, far too slightingly of the value of the iodide of potassium. Dr. Ziemssen, of Aix, spoke very disparagingly of the curative effects of the drug in the debate which took place last year in the Hunterian Society of London, and Dr. Schuster, of Aix, has put forward recently (*Deutsche Zeit. für Pract. Heilk.*, 1874) the following axioms, from which I greatly dissent: "Mercury has its best indications against the secondary and tertiary appearances of syphilis, such as the exanthems, gummy tumours, diseases of the bones, &c., although contra-indicated in diseases of the liver and kidney."

It would seem as if the proximity of Germany and of Aix-la-Chapelle had of late years influenced the opinions of Belgian practitioners of eminence on this point, for I find Dr. Thiry, of Brussels (*Presse Médicale Belge*, Nos. 37 and 38, 1874), going so far as to express himself as follows:

"Iodide of potassium does not possess any influence on a patient whilst under the influence of syphilis, and it is only when the syphilis has disappeared that we can destroy the poisonous effects of the mercury by the iodide of potassium, if mercury have been abused. Do not forget this (he adds), that iodide of potassium is of no effect in true syphilis, and if it is generally regarded as efficacious in the tertiary period of syphilis, it is because these accidents called tertiaries frequently have nothing to do with syphilis, and have been already treated unavailingly with mercury."

These quotations show well how strong an opposition is at present being made to the administration of iodide of potassium, even in the period when it is, as I hold, the most splendid of all the therapeutic agents we possess at this day.

M. Thiry seems to base his continuity of treatment by mercury in all periods of syphilis on the idea that

tertiary syphilis is still syphilis; and he cannot understand, he says, how a remedy which is useful at one time of the disease can prove of no service at another. But, it must be noticed, that when the tertiary period arrives, the disease has generally assumed a very different aspect from the one presented during the secondary period. Tertiary lesions are not contagious like secondary ones, and whilst a mother affected with roseola or syphilitic psoriasis, if pregnant, is almost certain to give birth to a diseased infant, we see continually women affected with tertiary disease of the throat, bones, &c., having perfectly healthy infants; for transmission to the offspring rarely, if ever, occurs in the true tertiary stage of the disease.

Nor is it allowable in these days to account for the utility of the iodide of potassium in tertiary syphilis by saying that when it does good it is because syphilis has been over-mercurialised. In this country, at least of late years, over-mercurialisation has been rare, and yet the value of the iodide of potassium is well-known among the foremost writers on syphilis in the United Kingdom.

No doubt, in former days, the abuse of mercury did, as I have witnessed, greatly aggravate the ensuing tertiary symptoms: but tertiaries arise without any mercury, and are curable when they thus arise just as rapidly by the iodide of potassium as when mercury has been previously used. This fact, indeed, led M.M. Perrin and Dolbeau, in the debate in the Société de Chirurgie in Paris, in 1867, to say that mercury could easily be discarded from the treatment of syphilis, since these gentlemen urged that tertiary symptoms, when they do appear, are so readily amenable to iodide of potassium, that we need not much dread them.

For my part, I hold that mercury is very injurious, as a rule, in all cases of true tertiary syphilis, which are diseases of debility, and require analeptics, not antidotes, as secondary symptoms do. Kupia is, for the most part, successfully treated by the iodide of potassium, whilst gummy tumours and nodes quickly improve under its use. When relapses take place we can only say that the remedy must again and again be used, and that for many years, if the disease prove obstinate and require it. Mercury often, in my experience, greatly aggravates tertiary symptoms. It is important especially to beware of it in tertiary sore-throat, or we shall let the patient sometimes lose his voice and powers of deglutition.

With regard to the dose of iodide of potassium, five grains, given thrice daily, are usually sufficient, except in cases of urgency, as in sloughing of the soft palate. In such cases, I give 15 or 20 grains, five or six times daily, in plenty of water; and I cannot say I remember to have had many disagreeable effects from such doses. I hear, however, of complete wasting of the testes occurring in one case cited by a Parisian author recently. Such effects are rarities. It seems to me that, at present, we can give no satisfactory reason why the iodide of potassium is curative in tertiary syphilis; but who is there who has any theory why quinine cures ague, or colchicum the pains of gout? It is precisely in such cases of specific action that we have most reason to be astonished at the miraculous and unexpected results; and whilst admiring ourselves, we should teach our juniors the art of medicine.

Summing up the results of this short discussion as to the antecedents and best treatment of tertiary syphilis, I would say that the evidence I have adduced seems to me to prove that tertiary syphilis is oftener seen in old persons and in persons of scrofulous or consumptive family history than in those who have sound constitutions and who are well fed and temperate.

From the late evidence of Drs. Ricord and Fournier, I have been led to adopt the conclusion that the administration of protracted courses of mercury in the early stages of the disease tends to ward off very materially the chances of tertiariism. I have, therefore, after a severe struggle with my former long-cherished beliefs, begun to imitate these gentlemen in giving several months of small doses of grey powder, or the green iodide of mercury (two or three grains of the former, or one grain of the latter in

the twenty-four hours) when my patients will take my advice. But what I desire to learn more about from the distinguished auditory around me is, whether the drug should be given for six months at a time, or, as Fournier advises, in an intermitted manner, for two years, giving ten mouths with, and fourteen months without it, or for how long? I confess that I am too much of a tyro in the matter of mercurial courses to offer an opinion on this point, and hence seek for further light from my respected brethren in this country. Of late their utterances in this matter have been, it seems to me, rather wanting in precision.

Should a patient with true tertiary syphilis come before me, I give large doses of iodide of potassium, either diluted largely with plain water, or contained in the decoction of sarsaparilla; and I obtain in the great majority of cases most admirable results. The only cases in which I admit that mercury may be useful, before the iodide has been tried, are those of the secundo-tertiary group, such as rupia and pustulo-crustaceous eruptions. In all other cases of tertiary syphilis, I strongly contend that mercury is, as a rule, injurious, and that it should not be used except as a last resource, when iodide of potassium has been tried and failed. Such are my present beliefs, held until greater knowledge and experience may qualify them.

Mr. President, I have to thank yourself and the Fellows of the Society for the kind way in which you have listened to my paper, and to express myself as having been greatly honoured in reading on the treatment of syphilis before such an eminent authority as yourself.

CLINICAL MEMORANDA.

Reported by JOHN W. MARTIN, M.D.,
Assistant-Surgeon Mayfield Factory Dispensary, Portlaw.

Pneumonia—Recovery by Lysas.

AUGUST 7th, 1874, I was asked to see M— P—, set. 17, by occupation a housemaid, two days ill; commenced with rigors, pain in the back and limbs, prostration, and sore-throat. When seen, face flushed, eyes suffused, tongue loaded, anorexia, constipation of the bowels, pungent heat of skin, and rapid respiration. Pulse 120. Ordered her into hospital.

Evening visit—found her complaining of a severe pain in the right side, preventing a full inspiration, and accelerating respiration. Affected part, dull, respiration tubular, and bronchophony. Much troubled with a short hard cough, attended with the characteristic rusty sputa of pneumonia. Tongue was cleaner, and the general febrile condition improved.

Treatment consisted of milk diet, turpentine stupe and hot poultices to the affected side, and the followins mixture:—

R. Bicarbonate of potash, } aa ʒij;
Citric acid, }
Liq. ammoniæ acetatis, ʒi;
Tr. aconitæ, ℥90;
Syrupi, ʒi;
Aqua ad ʒviij. M.

Two tablespoonfuls to be taken every fourth hour.

August 8th.—Passed a sleepless night; general symptoms, however, improved. Pulse 108; respiration 32; temperature 103°. Sputa not so deeply tinged with blood. Bowels moved, and the pain in the side diminished.

August 9th.—Slept well, and feels better. Had five motions since last visit. Pulse 104; respiration 34; temperature 103°. Heat of skin still very pungent. Treatment continued.

August 10th.—She was very delirious during the night. Got out of bed several times and walked about the floor, with difficulty being induced to go back again. About

6 a.m. she fell into a sound sleep, which continued up to the hour of visit, at 11 o'clock, when I found her lying on her back, the respiration tranquil, 24 per minute, pulse 60, and the temperature 95°. Skin quite cool; pain in the side gone. The well-marked dulness of the affected part unchanged. She had had no expectoration since the previous day. The tongue was clean and the bowels regular. Altogether she felt decidedly better.

August 11th.—A return of the expectoration, which was slightly tinged with blood. Pulse 76; respiration 24; temperature 98°.

August 12th.—Rusty sputa continued. Slight return of resonance and respiratory murmur in the seat of dulness. Had no cough or other unpleasant symptom. Pulse 72; respiration 22; temperature 98°. Directed a piece of Brown's blistering tissue to be applied to the side and left on for eight hours.

August 14th.—Blister acted nicely. Convalescent. Gave quinine in mixture and good nourishment.

The subsequent history of the case was one of steady convalescence, with a complete return of resonance and respiratory murmur to the portion of lung which had been consolidated. The rapid subsidence of all the symptoms upon August the 10th, the fifth day of illness, is worthy of remark.

INDIAN MEDICAL NOTES.—No. XXXII.

(FROM OUR SPECIAL CORRESPONDENT.)

MEERUT, January, 1875.

DOGMATIC.

THE month of January is here particularly cold in the early mornings, down to 26 in a tent, and at the Hills down to 12, wonderfully bracing to some constitutions, equally trying to weak hearts, lungs, livers, kidneys, or to those poisoned by syphilis, which, under the name of rheumatism or neuralgia, may torture terribly. Toothache, earache, irritation of the bladder, tendency to dropsy, to paralysis agitans, indeed, paralysis of any description, to Bright's disease, hæmaturia, diabetes *inter alia* may be induced or provoked by cold; so may tetanus. A woman, after the removal of a benignant mammary tumour the other day, was doing very well until one cold night a chill started tetanus, and although chloral for a time proved very valuable, she died. A half-caste woman, set. 45, with a history of cholera, epilepsy, uterine hæmorrhage provoked by polypi, with a sad story of years' ill-treatment, blows on the head and poor living, one cold night, a fortnight ago, found her jaw rigid, so that now with the greatest difficulty is she fed. The wish is to enter into this interesting case when completed. Every afternoon spasms come on, the silly, puffy, grinning face becomes more ghastly, a convulsion induces spasm of the diaphragm, both arms work up from the elbows, the legs are quiet yet rigid, she suffers great pain, the pulse feeble, the temperature often high, yet capricious, the body bathed in perspiration, the bowels constipated, the bladder irritable, yet neither opisthotonos nor emprosthotonos. The convulsion lasts but a short time, leaving the patient very enfeebled, moaning and sobbing during sleep. The tongue, of course, cannot be seen; for more than fourteen days the jaws are locked, just allowing liquids to trickle in. Kept very warm, fed on milk, beef-juce, beef-tea, eggs. She has large doses of iodide of potassium during the day, chloral at night; blisters are applied to neck and temples, the bowels relieved by turpentine, the spine rubbed with sedative liniments; neither chloroform nor henbane did any good; the wish was to try Calabar bean—not procurable. The intellect remains marvellously clear, the speech is guttural, yet by signs her replies are intelligible. Probably, tape-worms have added to the causes inducing chronic idiopathic tetanus, the prognosis most unfavourable; change of life, too, must be considered. Mark my words, she will die, and the post-

mortem will throw no direct light. Tetanus occurs in India after delivery occasionally, and at quickening in England; but I must not drift into this extensive subject, for infantile trismus is a familiar disease easy to describe. This poor woman somehow reminded me of a case of hydrophobia, treated years ago, in certain respects, so it did of chorea, and the clear intellect characteristic of that pitiable, terrible condition termed locomotor ataxy, when we can give no hope to the patient, who, to the uninitiated, appears only to be temporarily ill. Rheumatism is another disease which tries the natives badly fed, the poorly clad, who, exposed to the sun by day, have scanty bedding on cold wet ground at night. As a medical student it was my bad fortune to have two attacks of rheumatic fever of severe type, yet during several years of professional life in England, Ireland, besides the extremes of temperature of Canadian cold and Indian heat, the pains never recur; yet the damp cold or the damp heat of Northern India racks certain constitutions irretrievably. When under canvas the sword and spurs are wet with dew, and the air pierces the very marrow-bones; then do the old toppers or the syphilitised complain of the pains. Under the head of rheumatism, 26,155 cases were treated in 10 years in Bengal, of whom 28 died, 1,870 were invalided. Of rheumatic fever I have treated two genuine cases here, and ahoals at home—trusting to alkalies, colchicum, sedatives, wrapping up the joints, anticipating pericarditis, plenty of blankets, no sheets, splendid nursing, &c. As a rule, the disease is a safe one, yet very wearing to patient, nurse and practitioner; it must run allotted course, all abortive measures mischievous. The greatest sufferers are suckling women inclined to hæmorrhages. Dry heat and cold are very tolerable, provided due precaution be adopted. If you lurch severely, then go about with a skimpy helmet—look out for sunstroke in May; if careless about warm clothing, diet, and abdominal protection in January, do not blame India, or crab climate, when colic, dysentery, or rheumatism supervene. Some men grow very fat in the cold season—sleek-headed men, such as sleep at night, sleep at meals, after meals, at all hours: thus fatty degeneration goes on—the minute cerebral vessels become weaker, perhaps give way; so to avoid death, paralysis, or brain softening, exercise and dietetics must be enforced. Fever, in the month of February, still runs on in its puzzling way; for those who go in for subsoil theories are reminded of Mean Meer, where, with scanty rainfall and the water at a great depth, the fever may be as virulent as ever. In the last Blue Book is reiterated the statement, this time by Dr. Munro, C.B., that no such poison as malaria exists. Certain conditions of electrical character, induced by heat and moisture, act on the sympathetic nervous system, causing fever by paralysis. Intermittent, remittent, jungle, yellow fever, cholera, heat apoplexy are different degrees of such paralysis, which at the onset may be controlled by quinine. Doctors differ. With Uriah Heep humility, many of us, knowing nothing, say nothing, for speech is as silver and silence as gold. Let us see what the divine William writes:

My wind cooling my broth would blow me to an ague;
Here let them lie till famine and the ague eat them up,
As dim and meagre as an ague's fit.
Home without boots in foul weather, how 'scapes he ague.
Worse than the sun in March, this praise doth nourish ague,
Ague which hath made you lean;
And danger like an ague subtly taints even then
When we sit idly in the sun.

With Bryden's Tables and Shakespeare many a pleasant hour may be spent by those curious about certain matters, for the medical chronicles of England wonderfully harmonise with Indian diseases of to-day. There are certain remedies very valuable in intermittent fever—for instance, emetics, also podophyllin, turpentine, chloride of ammonia, iron, arsenic, quinine, the frequent administration of powders containing one-eighth of a grain of tartar emetic combined with five grains of nitrate of potash, not forgetting opium, paregoric, chlorodyne, and chloral. The last 30 cases of diarrhoea all had the same, an ounce

of castor-oil, a drachm of turpentine, ten minims of laudanum, horizontal position, no food. Should diarrhoea continue, then ipecacuanha, commencing with five-grain doses. Very satisfactory results, after years tried of every treatment. A day or two ago, examining the ilium of a case termed enteric, certain medical men were not content, the lesions not sufficiently characteristic; it is so difficult to discriminate between remittent and enteric. A man comes in with headache, lassitude, muscular pain, epistaxis, gurgling, yet no diarrhoea, the abdominal tension very trifling; yet he dies of enteric, and his evacuations are dangerous when inhaled by one man, who develops enteric, yet other persons, young and weakly, escape. This subject is ever on my mind. I believe the same poison excites suppurative inflammation of the liver, besides dysentery. One colleague states that enteric burst out in the bush in New Zealand. Another insists on the germ introduction into constitutions, there to flourish or die, according to the soil, congenial or otherwise. At certain seasons, in certain places, the poison, encouraged by heat, moisture, and faulty sanitation, is there looking out for those susceptible; so the fire kindles, to go out when atmospheric conditions change. From one case the disease runs on to the next person, after an incubation of three weeks, possibly longer; but here head symptoms are very prominent, not so the eruption, which may or may not appear. Nor do we require, or gain, or learn anything by the eruption when the other points are as plain as a pikestaff. Enteric confers no immunity from ague. Conversely, some men appear to pick up wonderfully, to look stronger. This letter, written hastily to catch the post, reads unsatisfactorily, somewhat suggestive of the lines, "I am Sir Oracle, and when I open my lips, let no dog bark."

CASE OF DOUBLE AMPUTATION OF THE THIGH IN COUNTRY PRACTICE.

By ROBERT MORTON, M.B., F.R.C.S.I.,
Castleblayney, Co. Monaghan.

I HAVE allowed some time to elapse since this case occurred, because I did not think any great interest attached to it more than the severity of the accident, unless it be in a statistical point of view.

While medical officer of Bellaghy Dispensary, Co. Derry, I was hurriedly sent for on the 21st January, 1867, to see an engine-driver who had been hurt in Castledawson Mill. The mill was worked by water-pure, but that not being sufficient, steam was added, and the shaft connecting the steam machinery with the mill passed through a small house built to protect the shaft itself and to allow nothing to approach it. This shaft required to be oiled occasionally, and means for doing so through the roof were provided; but this unfortunate man, having on an outside coat, unlocked the door and went into this small chamber with his oil-can. He was caught by the shaft and whirled round, revolving from twenty to thirty times a minute; as he was caught near the shoulder and behind it, his legs struck the clay floor and one brick wall in each revolution. From the time his position was seen (the noise of machinery drowning his cries) to the time of his release must have been from seven to ten minutes; but he, poor fellow, was positive that he was in two hours. When I reached him, 4 p.m., he had been removed a short distance to his own house and lay there cold and pulseless, hardly sensible—his hands were a little battered and his body safe, but on cutting off his trousers both knee-joints lay open, worn open, one patella turned down on the leg and the other standing straight out from the joint, both separated from the extensors; the tibia and femur were exposed, and sand ground into their worn surfaces. Though the knees were equally bad, the left leg was most injured, but both were scraped and bruised, the toes and nails much shattered. I sponged quantities of clay and sand out of the joints, and

put up each leg on a splint with foot-board, like fractured patella, with warm water dressing, hot brandy, blankets, &c.

9 p.m.—Slight reaction, with thirst and vomiting, intense pain, described as if his legs were in the fire.

Jan. 22.—Still semi-collapse; vomiting incessant; passed the night in a sort of stupor.

I was now joined by the late Dr. Vesey, of Magherafelt, who heard of the accident and came unasked to my assistance, and was indefatigable in his kindness through the entire case. I had thus the help of that bold and successful operator, excellent surgeon, and sincere friend.

Twenty-four hours after the receipt of the injury reaction was not sufficiently established to do anything; but as soon as we could we decided on amputating one or both thighs together, as the only chance of saving his life; and as the patient was young, about twenty years old, strong, healthy, and temperate, a better-developed specimen of a man than is usually seen, we hoped for the best. Besides, he himself was anxious that anything should be done to ease his intense pain and plenty of friends would assist him in case he survived.

23rd.—He seemed able, and was willing, to risk amputation of the left thigh, this was the most painful. The joint was full of fetid pus and blood, the leg swollen, dark and glazed, while his pulse had risen to 120.

Dr. McMullen kindly gave chloroform, and assisted by the late Dr. Vesey and the present Dr. Vesey, then a student, I amputated by circular method about the centre of the femur. This being as far as I could go from the trunk and secure a flap even by this operation, the tissues about the joint showing a much greater extent of injury on this than the preceding day, but two arteries required ligature. He showed no symptoms of shock, but got great relief from pain on that side, and on the evening of this day was better than any time since the accident.

24th.—Much the same way as on the morning of the 23rd. Is now anxious to have the other limb off. Pus welling up in the joint and escaping through the bed, while below the knee the leg was discoloured and swollen, like the left leg the day before. Accordingly, with the same valuable and friendly assistance I removed the right thigh in the same situation as the left by the same operation. Six arteries required ligature.

At 3 p.m. he was wonderfully recovered, and pain relieved; at 9 p.m. still more so. Drank freely beef-tea and some brandy, though the stomach sometimes rejected it.

25th.—Bowels acted freely; urine passed naturally; pulse 111, and as strong as at any time since the accident; his spirits actually cheerful.

26th.—Dressed left stump with Dr. Vesey, and examined the right; both looked first-rate, and no bad symptoms of any kind.

27th.—Had a bad night, but seemed better; pulse 102, weak. This day congestion of the left lung seemed imminent, but disappeared towards evening.

28th.—Dressed both stumps; they appeared to be all that could be desired; while he was stronger, more cheerful and hopeful than before; pulse 105.

29th.—Restless, no sleep; pulse 111.

8 p.m.—Pulse 120; delirious, complaining bitterly of the weight of right stump, bandages not tight, and no pain on pressure.

30th, 9 a.m.—Delirious all night, and still so; pulse 120, and weak; right stump still painful, so bandages were opened, as thigh seemed swollen, and there was for the first time pain on pressure along inside of thigh and groin; veins hard and knotty.

1 p.m.—With Dr. Vesey dressed both stumps; the right had swelled so rapidly since 9 o'clock that the bandages were tight again; the edges of the wound were so swollen that we cut the sutures, when the flaps fell open, showing one mass of slough, with the femoral artery pulsating dangerously. As a bandage could not be borne, we merely put on a large carrot and linseed-meal poultice, which gave great ease. Nothing unusual about the left stump. He remained delirious till 5 p.m. next day.

31st.—He was quite calm, though sinking, and died at 6.30 p.m. with the composure and bravery of a Christian.

The extent of the injury in this case left us nothing to hope for—present pain intense and death in the future. Whatever idea might be entertained of removing the injured ends of femur and tibia of either or both limbs without resorting to amputation was destroyed by the extent of damage shown by the soft parts on the second day. The constitution, courage, and strength of the poor fellow could not be surpassed; his agony was severe, and his prospects of livelihood if he survived promised well. Up to the fifth day from the last, and the sixth from the first operation, he went on most satisfactorily. The fact of two ligatures being required for the first and six for the second operation is, I think, explained by the change caused in the circulation by the first amputation, or a difference in the point of division of the arteries, the section being in the same place for both limbs.

After the 29th, delirium, rapid weak pulse, œdema of right stump extending over abdomen and scrotum, tympanitis, pain on pressure over a knotty femoral vein, with sloughing stumps full of unhealthy pus, that seemed to burrow into the intercellular tissue between the muscles of the thigh, and could be squeezed out, with rapid and laborious breathing, made the final cause of death appear to be phlebitis and pyæmia, so rapidly fatal to a vitality already prostrated that no time was given for other symptoms to become developed. He never had a rigor or coated tongue, and urine was well secreted all the time. For the last two days the distressing complication of secondary hæmorrhage was never absent from my mind, and if he had lived much longer would probably have happened. The hygienic state of the patient was not bad, though not all that could be desired; we had great difficulty in keeping an even temperature, on account of the severe winter weather just at that time.

Hospital Reports.

LONDON HOSPITAL.

(Under the care of Mr. RIVINGTON.)

Punctured Wound of Chest Penetrating the Lung—Pleuro-pneumonia—Recovery.

JOHN BOLETO, 23, a Greek sailor, was admitted March 15th, 1872. In a quarrel with a shipmate he was stabbed in the chest with the blade of a clasp-knife. On admission, at 1 a.m., he was found to have received a punctured wound three-quarters of an inch long, close to the right nipple. He had lost a great deal of blood, was very weak and pale, and there was external emphysema. Pulse 84, feeble; respiration rather laboured, 32; temperature 99.4°. The skin was moist and cool, neither cold nor clammy.

1.15 a.m. Sent to bed, an extra nurse ordered, and an injection of ergotine, gr. iij., administered; ice applied to the chest. Everything he drank was ordered to be iced. He fell asleep soon after he was sent to bed.

4 a.m. Temperature 101.0°; pulse 108; respiration 40; breathing heavy and laboured; pulse feeble; skin hot and dry; feet warm; pain in the right loin; constrictive feelings in the chest. He could not speak more than a few words of English, and could only express his wants by signs. He evidently wished the bandage removed from his chest, and tried to explain his sense of its inutilty. Kept on saying, "Me dead by-and-by."

10 a.m. Pulse stronger and fuller; skin very hot; troublesome cough, but no expectoration; tongue rather brown; not so much pain. As he had passed no water since admission, the bladder was emptied with the catheter. Urine high coloured, sp. gr. 1.025, no albumen.

The stethoscope revealed crepitation at the seat of injury; dulness on percussion.

9 p.m. Pulse feeble; hot skin; profuse perspiration;

temperature 101.5°; no vomiting; patient took a little milk and beef-tea, but disliked the ice. Wound redressed.

March 16th, 3 A.M. Patient was asleep, and had been asleep two hours and a half, but previously had been extremely restless. He had passed a large quantity of urine; skin cooler and moister; pulse feeble; respiration quicker. Poultice applied to the chest.

10 A.M. Wound redressed. Still complaining of the pain in his side; just above the middle of the right iliac crest, and still objecting to the bandage round his chest. Temperature 100.6°; skin hot and dry; dulness on percussion; tubular breathing at the back of the chest; crepitation and friction sound in front. Anxious aspect.

17th. Less anxiety of expression; tongue moist; skin cool; pulse fuller, less feeble, and frequent, 90; perspiration free; bowels freely opened by house medicine; local symptoms the same as before.

18th. Restless night; more anxiety; tongue brown and dry; no cough; pulse, respiration, and temperature had all gone down nearly to the normal standard, and he was free from pain; food taken fairly; perspiration less.

7.30 P.M. Improvement confirmed.

19th. Passed a good night. Abnormal sounds in chest fast disappearing; tongue cleaner; condition greatly improved.

20th, 21st. Convalescence established.

22nd. Allowed to get up.

24th. As he complained of some pain in the right side of his chest, he was directed to remain in bed; otherwise he continued well, and took his food with appetite and relish.

He remained under observation for another month, and was discharged cured on April 20th.

It is probable that the injury caused some effusion of blood into the pleura, with a little local inflammation, quickly ending in absorption and resolution.

Deep Punctured Wound in Left Supra-clavicular Region and Incised Wound of Right Arm—Recovery.

Wm. McIntyre, lighterman, æt. 28, was admitted on September 1st, 1872, about 2 a.m., suffering from wounds which he had received in a quarrel with his brother. He was not intoxicated, but had been drinking freely. There was a wound in the skin an inch in length, running from before backwards directly above the middle of the upper margin of the left scapula, and extending to a depth of two inches. Both arterial and venous blood oozed from the wound, and it was thought by the house-surgeon that a branch of artery and vein (possibly the transverse cervical) had been divided. Another wound was situated on the right arm, over the middle of the biceps, and extended transversely through the skin and fascia for two inches. The patient appeared to be suffering from loss of blood.

The wound in the neck was closed with a single wire suture, and a graduated compress was applied to arrest the bleeding. The wound in the arm was also closed.

Sept. 2nd. Compress and sutures removed from both wounds, which had healed partially by first intention. Wet lint applied to incised wound, and punctured wound closed with lint and collodion. The patient complained of slight pain in the neck and upper part and left side of the chest, increased on taking a deep inspiration. After the application of the collodion the pain in the chest and neck gradually disappeared. The temperature continued normal throughout. In a few days he left the hospital, cured.

Punctured Wound of Abdomen—Protrusion of Omentum—Removal of Part and Return of the rest of the Omentum into the Abdomen—Recovery.

Henry Walker, 26, a healthy man, was admitted on Sept. 29th, 1872. He was fighting with his brother and was stabbed by him. On admission there was a skin-wound an inch and a half long in the lumbar region, with a direction obliquely downwards and inwards. The knife entered the abdominal cavity about an inch below the puncture in the skin. A piece of omentum, slightly torn,

protruded for nearly two inches, and could not be reduced. Mr. Cooke, the house-surgeon, placed a catgut ligature round it, cut off the protruding portion, enlarged the wound, returned the stump into the abdominal cavity, and closed the opening with lint and collodion, and applied a pad and bandage. Tinct. opii ℞v., every four hours.

Sept. 30. Temperature 100.6°; pulse 88; respiration 22.

Oct. 1st. Temperature, morning, 100°; evening, 100.4°; pulse 70; respiration 20.

Through the restlessness of the patient the dressings were shifted, and the collodion covering came off. The wound was washed with warm water, stitches were removed, narrow strips of strapping were applied, and a pad and bandage adjusted over all.

Oct. 2. Temperature 100.6°; pulse 78; respiration 26. Redressed.

Oct. 3. Temperature 101.2°; pulse 76; respiration 25. Redressed.

Oct. 4. Temperature 99.2°; pulse 80; respiration 20.

Tinct. opii stopped. Castor-oil enema given.

Below the wound a collection of pus had formed under the skin, and was evacuated. No symptoms of peritonitis. 5th. Temperature 98.4°; pulse 66; respiration 20.

6th. Temperature 99°; pulse 78; respiration 18.

Some pus discharged for several days from the wound. The progress was altogether satisfactory; the temperature, pulse, and breathing remaining quite natural.

By the 15th only a small opening remained, quite of a superficial character. Soon afterwards the patient was discharged cured.

C. J. B. WILLIAMS, M.D., F.R.S., President, in the Chair.

CONTRIBUTIONS TO THE HISTORY OF LARYNGEAL PHTHISIS.

By WILLIAM MARCET, M.D., F.R.S.

DR. MARCET divided his paper into two parts; the first being a short account of the history of laryngeal phthisis, and the second a record of his own observations on the subject. The second part began with a remark that laryngeal phthisis is both a symptom and an extension of a pre-existing disease. It is a symptom, because, when its existence is clearly established by laryngoscopic examination, there is no doubt that the lungs either are or will shortly become tubercular, if not obviously so at the time; it is an extension of a disease, because, as a rule (he did not say invariably, although it may be so), the pulmonary tissue first becomes the seat of tubercular growth, mischief appearing subsequently in the larynx. The author's former connection with the Hospital for Consumption and Diseases of the Chest at Brompton had given him a wide field for the investigation of laryngeal phthisis, of which he had availed himself; and he reported in a tabular form 70 cases of disease of the larynx in phthisis, in which both the physical signs of the chest and laryngoscopic appearances were faithfully recorded. This formed the groundwork of his communication. The author inquired into the main predisposing cause of laryngeal phthisis; and, after examining the various trades and employments recorded in 57 cases, came to the conclusion that excessive use of the vocal organ is hardly, if at all, a predisposing cause of that affection. Out of the 57 cases, 30, or a proportion of about 53 per cent., were employed on indoors or sedentary and home work; while, of 309 cases of phthisis attended by the author at the hospital in 1869, all of which were free from laryngeal disease, about 80 were employed on indoor and sedentary work, giving a proportion of 26 per cent. It would therefore appear that sedentary and indoor work has a marked influence as a predisposing cause of laryngeal phthisis. A case was recorded, however, where the disease broke out in a butcher's assistant, whose business it was to call out the weights of the meat on

the scale. This appears to be a very laborious work for the vocal organ. It was remarkable that there was not a single hawk on the list of cases of laryngeal phthisis. Deficient out-of-door exercise and want of pure air together, it might safely be added, with neglect of the rules of hygiene and mental anxiety, are the main predisposing causes of laryngeal phthisis. The disease, therefore, appeared to be a low form of consumption, and requires as much attention to be paid to the general state of health as to the local mischief, if not more. The author next alluded to a state of weakness of the muscles of the vocal cords occasionally met with in consumption, without there being any organic change in the larynx; and observed that in these cases the tensor muscles of the cords appear more often affected than the adductors, while in hysteria the latter set of muscles are more commonly at fault. Cases were given illustrating both kinds of affections. He afterwards described the appearance of the larynx in laryngeal phthisis, and insisted on the presence of a whitey milky, probably purulent, mucous fluid in the laryngeal cavity as a means of diagnosis of phthisis. The prognosis, where organic disease is detected in the larynx, in cases of consumption, is not favourable; still, much can be done towards relieving the pain and distress in the throat. The author then stated that there is nothing contagious in laryngeal phthisis, although the expired air from the chest of a person suffering from the disease may be peculiarly irritating to the throat of another in good health. He thought that this irritating property of inspired air equally applies to phthisis, without any affection of the larynx; indeed, he found the air expired by a healthy individual often irritating to the larynx of another person. He cited his own experience on the subject, and remarked that his throat frequently suffered from irritation in consequence of his being called upon to breathe near the mouths of his patients while using the laryngoscope in a succession of cases. Some remarks followed as to the unhealthy character of expired air in other respects; and the author then described the treatment. The application to the larynx of a solution of iodine in olive-oil, or of bromide of potassium in glycerine and gum-water, relieved the pain; and scarifications, when the larynx was much swollen, proved beneficial. Inhalations of iodine were also sometimes used with advantage. When the laryngeal mucous membrane was neither ulcerated nor much swollen, faradisation of the muscles of the larynx often succeeded in improving the voice. A few remarks were here introduced on climate. The author believed that, wherever those who suffer from consumption in an acute form may be living, except, perhaps, if residing high up in the mountains, they will, as a rule, derive benefit from removing to a place higher up, although, perhaps, not distant from their residence, and possibly not more than from one hundred to three hundred feet above it. The post-mortem changes in the larynx were shortly noticed, and then the author considered the cases he had brought forward. He related the history of two patients with laryngeal affections, who both recovered; one of them exhibited rather suspicious symptoms of phthisis, while the other case was one of acute laryngitis, with aphonia accompanying pulmonary congestion. The conclusions derived from the consideration of the table of 70 cases of diseased larynx in phthisis, in all of which the physical signs of the chest were reported, were as follows: 1. More men than women were affected, in the proportion of about two of the former to one of the latter. 2. The ages recorded in 55 instances appeared to show that most cases of laryngeal phthisis are met with between the ages of 20 and 30 years, or at that of 30 and above 20. Dr. J. E. Pollock states ("Elements of Prognosis in Consumption") that there is a large preponderance of cases of phthisis between those ages; and therefore, as far as age is concerned, the predisposition appears to apply equally to consumption, whether the throat be affected or not. 3. Out of 70 cases of phthisis, in which the larynx was affected, eight of them exhibited no visible organic change, with the exception of slight redness with congestion in two of the eight cases; tension of the vocal cords was deficient in five; in the three other cases, adduction of the cords was deficient in two, and abnormal in one. 4. In 31 cases out of the 70 the epiglottis was affected (a statement of the nature of the change in every case was given). 5. Only 13 cases were recorded of positive ulceration of the larynx out of the 70—this proportion appearing rather smaller than might have been anticipated. Patients with laryngeal ulcerations are, as a rule, older than those whose larynx, although affected, is not ulcerated. The mean age of the patients suffering from ulcerations in the larynx was 38 years,

while the mean age of those whose larynx was free from ulceration was 29·7 years; the author concluding that want of nutrition due to age appears to act as a predisposing cause of laryngeal ulceration. 6. Dysphagia, or difficulty in swallowing, was noted in 14 cases; but this symptom may, perhaps, have existed in others, although not recorded. As a rule, there is pain and dysphagia whenever the epiglottis is affected; although, where that organ is merely congested and streaked (without being indurated) by the presence of enlarged vessels, the discomfort may be very slight indeed, and hardly noticed by the patient. 7. Aphonia, or some alteration of the voice, was reported in 59 out of the 70 cases. Of the other 11, it was concluded from the state of the larynx that the voice was probably weak or otherwise affected in 9.

ANIMALCULES IN PUS.

THE great and ever interesting question of spontaneous generation has just been revived by a communication of recent date, addressed to the Academy of Sciences of Paris. M. Albert Bergeron, awakened by the report of Dr. Gosselin upon cotton-wool dressings of wounds and the place to be assigned to animalcules in the production of septicæmia, has had the lucky thought of making a microscopic examination of the pus from all kinds of abscesses met with by him for some time past, and with the following results:

In a certain number of cases of abscess he has ascertained the presence of microscopic animalcules (vibrios, or other species), whilst he has found none in others. The pus containing microscopic organisms belonged exclusively to abscesses in adults or old persons. Other abscesses, noticed in children, contained none. And, besides these, vibrios were not met with in cold abscesses, either in the adult or in infants. Such are the facts as observed.

The conclusions seem clear enough, and are, firstly, that in an organic liquid, when the diseased cavities are hermetically sealed, and quite away from the influence of the air and the germs it contains, inferior germs may appear; and secondly, that this only occurs at certain times of life, or in peculiar organic conditions.

M. Pasteur has been much excited by this curious discovery, as may well be imagined. This eminent chemist, thinking that the Academy of Sciences might have had enough of the question of spontaneous generation, took the subject to the Academy of Medicine, and there de-

manded that a committee should be appointed to examine the question, and ascertain how far M. Bergeron was correct in his facts. But the constitution of the Academy of Medicine does not permit such a committee, it appears, to be appointed.

Dra. Legros and Onimus, it seems, in 1873, presented to the Academy of Sciences the *résumé* of some experiments tending to demonstrate the spontaneous generation of beer-wort. The fundamental experiment of these gentlemen consisted in plunging, in a vessel containing sugar and water and wort, an egg previously deprived of its calcareous envelope, whilst the other membrane was left intact. Some days subsequently the beer-yeast was found in the interior of the egg. M. Pasteur repeated the experiment, and denied that the asserted fact was true.

M. Pasteur has made a great step in the science of fermentation by carefully circumscribing it and rigorously defining what is to be meant by the word fermentation. In his eyes there is no fermentation without ferments—i.e., without the intervention of the germs of living organisms which may be seen in the microscope. These microscopic organisms are proper organised bodies, and not only organised matters, like those albuminoid substances the presence of which, according to Trécul and Frémy, alone suffices to provoke fermentation. It is a great question to determine, indeed, if all fermentation, and especially putrid or septic fermentation, which most interests practitioners of medicine, is the product of a special living organism, the germ of which comes from without, or whether the substances which have been gifted with life carry within themselves the germ of their decomposition.

Dr. Gosselin remarks that Pasteur, whilst developing excellent thoughts about the difficulty of well observing the results of experience, and pointing out the errors committed by some of his opponents, may have left an impression on his hearers that his criticisms were made against the facts discovered by M. Bergeron. But, says M. Gosselin, that which Bergeron has said, he has seen; and what he has seen is that there are bacteria and vibrios in "hot abscesses" which have just been opened. These are observations easily made, and not delicate experiments like these referred to by Pasteur.

It suffices to have some tubes well washed with hypsulphite of soda, and heated with carefully distilled water and plates of glass, a power of 500 or 600 diameters, and a certain habit of using such instruments. One fact remains ascertained, and that is that the pus from hot abscesses sometimes (not always) contains vibrios and bacteria, showing a first degree of putrid alteration. This is not a question of spontaneous generation at all, says Dr. Gosselin, but simply one of pathological physiology and of clinical observation.

For many years past surgeons have been preoccupied with the thought that the great fevers which complicate wounds are infectious, and that they are caused by the products resulting from the decomposition of organic liquids, especially of pus. Thinking thus, they have more and more studied this liquid. We have for some time known how it is very putrescible in air, and that in the commonest form of its decomposition it gives rise to products of bad odour, sulphuretted hydrogen, sulphide of

ammonium, &c. When microscopic observations were invoked, it was found in addition to this, that pus, when it became putrid in the air, became filled with vibrios and bacteria; and it was for a moment hoped that in this there had been discovered a means of appreciating the evil effects of pus. Dressings have been invented, some having the property of preventing the formation of vibrios, and others of destroying them when formed.

Facts have, to a certain extent, responded to expectation; for the therapeutic remedies suggested by recent experiment have given good results. But this was not by preventing vibrios, or making them disappear, says Dr. Gosselin, but rather by preventing the ulterior and graver decompositions, the possibility of which was indicated by the vibrios to a certain extent. In the actual state of our knowledge, in a word, these microscopic animalcules are not the dangerous agents against which we have to fight; they are the forerunners which authorise us to be on our guard against the poison of the latter; and in this point of view it is not uninteresting to study them. It is from such ideas that M.M. Bergeron and Gosselin wished to find perchance pus in certain persons was not putrescible before the abscess was opened and contained bacteria. Gosselin was led to this research by the recollection of having seen hot abscesses, foetid, and filled with gas, far advanced in putrid alteration, which, nevertheless, had no communication with the air. It seems that bacteria are also sometimes found in the urine, whether acid or ammoniacal, of persons who had never been sounded, or sounded long ago. Dr. Gosselin, on this account, does not admit the spontaneous generation of such organisms in the liquids referred to. He would prefer, he adds, perhaps, to give no opinion on the subject; but, if obliged to pronounce himself, he would say that, carried away by the very beautiful demonstrations given by Pasteur in the case of other ferments, and, above all by the preventive deductions of such utility derived from these, he would ask whether there may not be an indirect way through which the germs capable of exciting fermentation may enter into the cavities of hot abscesses not directly communicating with the air. The answer, he thinks, is not very difficult. Why may such ferments not enter through the digestive organs, or lungs? Are they not inhaled with the air at each inspiration? Then invisible and intangible as they are, may they not with the oxygen pass through the thin walls of the pulmonary vesicles and their vessels and enter the blood. It must, in short, be admitted that our body is surrounded with ferments. Why should there be none of these inside? So long as these do not find a medium appropriate to their evolution, they remain inactive and infensively; but let this medium appear, like pus formed at the expense of the blood, in acute inflammation, may not these ferments then commence their action in decomposing the blood and forming vibrios and bacteria?

It is to be hoped that Pasteur and other able experimenters will try to unravel this difficult point. According to Gosselin's discovery, it seems that the use of carbolic dressing cannot be so important as supposed, since the very abscesses and wounds it has been so much employed for are the ones which contain vibrios of themselves, not derived necessarily from the air.

THE FRAUDULENT TRADING PROTECTION BILL.

WE are gratified to observe that the leading journals of the United Kingdom—lay and professional—have taken sides with the victimised consumer against Mr. Sclater-Booth's Bill to enable manufacturers and traders to cheat under the protection of the law, and we see with much pleasure that the condemnation of this proposal by the *MEDICAL PRESS AND CIRCULAR* has served as the text for warm protests by the *Pall Mall Gazette*, the *York Herald*, and other leading metropolitan and provincial journals. The outcry on the part of the public against this Bill is, in fact, unanimous, and the defence of it by the trade journals, though vehement, yet weak and inconclusive. The measure is truly one of the most audacious bills for Parliamentary sanction for trade malpractices that has ever come before the House, and the confidence of the shopkeeping interest in their own legislative strength is manifested by the fact that they have boldly demanded such protection as the bill gives them. We repeat, without fear of contradiction by any person who is conversant with the working of the present law, that the clauses of Mr. Sclater-Booth's Bill would render impossible any successful prosecution of any adulteration, however gross, except in the case of a manifestly poisonous admixture, and even in that case a conviction would be almost unattainable. The analyst of the county of Devon writes in corroboration of our view in the *National Food Reformer*, as follows:—

"The 4th, 5th, and 6th clauses each contain the word *knowingly*. I recommend this word to honest tradesmen, and point out that if it passes in the present state it will be to their manifest advantage to dispense their *mixtures* by the hands of some unintelligent assistant who does not nor will not know anything. I would also point out to *honest* tradesmen that the 8th clause contains no less than five loopholes, or I should say large, convenient, and airy openings through which they may walk out of court with head erect and character unstained.

"Mr. Wine Merchant, I hold in my hand an analysis showing your sherry is brandied and plastered, and therefore vilely adulterated.' 'Excuse me, Sir, it is mixed therewith for the purpose of preserving it' (sect. 6).

"My milk is watered; my tea is sanded; my vinegar is acidulated with mineral acid. The milkman, the grocer, the distiller, reply to my vehement accusation in indignant chorus—

"The usages of trade, Sir! the usages of trade, sir!' (section 6). But the most amusing part of the 6th section is what I may call its postscript, except where the article is unavoidably mixed with extraneous matter. Now there are few impurities which an ingenious advocate could not show were entirely unavoidable."

We cannot justify the presence of such provisions in the measure on any charitable ground, and can only look upon them as deliberately framed to enable traders and manufacturers to make dishonest profits by making and selling articles which are not what they profess to be, and not what the purchaser pays for or would accept if he knew their ingredients.

Be it remembered that we have no desire to place any restriction upon manufacture, trade, or consumption, except the one obligation that the admixture shall not be poisonous. We are aware that, in practice, it would be impossible to obtain complete purity, and improper to forbid the public to buy mixed articles if taste or economy prompted them to do so. Heartily as we have rejoiced

over the punishment of adulterators of tea, milk, mustard, cocoa, and other articles whose sophistication may be said to be innocuous, we have never argued that consumers should be precluded from buying these articles if they chose—with a full knowledge—to do so. Mustard may be as good with flour and turmeric as without it; cocoa may be as nutritious and more palatable with starch and sugar as without it; and if consumers think so there can be no reason why manufacturers should be prevented making up such mixtures for them; but there is every reason—in public morality if in no other way—why the manufacturer should not be allowed to make up any mixture he likes and sell it, at a vast profit, with a tacit warranty that it is a pure, genuine article, and by means of this implied guarantee to induce the consumer to buy that which he might refuse to touch if he knew its constituents, and which he certainly would refuse to pay for at the rate at which it is charged to him. This transaction is—rendered into English—a plain obtaining of money under a false pretence, and yet it is what we see a Committee of the House of Commons suggesting and Mr. Sclater-Booth proposing. Is there any hardship on the trader involved in asking him to state plainly to his customer what he is selling? If the article is good, cheap, and palatable, it will be bought with more readiness, because the purchaser has confidence in it; if it be noxious, useless, or nasty surely its sale ought not to be aided by permitting the employment of any false pretence. We urge, therefore—however Utopian the proposition may appear to be—that an article shall be described as what it is by a plain, readable label. We must have no subterfuges and no attempts to hoodwink the customer by an insufficient description. A cocoa-maker who wishes to sell a mixture of starch, sugar, and cocoa, at say 4d. a package, instead of genuine cocoa at 6d., should not be permitted to veil the admixture by calling the mixture "homœopathic cocoa," or "improved cocoa," or any other such euphonistic title. His label should be plainly "cocoa mixture, containing so much starch and so much sugar," with any laudatory additions which he may suppose will please the customer. We insist that the poor customer would, in the long run, prefer to buy such an article for 4d. to paying 6d. for the pure material, and the manufacturer would be none the worse for adhering to the simple truth. He would receive the honest profit of his trade, and we maintain that the law should forbid him to receive any other; and yet Mr. Sclater-Booth gravely suggests that all such fraudulent profits are to be tolerated so long as they are "the usages of the trade."

Against one of Mr. Sclater-Booth's proposals we have a special protest to make—that which requires that a vendor shall *knowingly* sell an impure article before a conviction can be obtained. There can be no other reason for such a proviso except the protection of frauds in detail, because it must be evident that no proof of guilty knowledge could be procured except by the confession of the culprit himself, or the proof that the person from whom he bought the article explicitly told him of its constitution, and as such proofs are obviously impossible, Mr. Sclater-Booth might as well simplify his bill by reducing it to one clause, to the effect that no retail dealer should ever be prosecuted for adulteration.

Surely it is neither a hardship nor a departure from "the usage of trade" to throw the onus upon the retail dealer. If a railway contractor specifies for the best steel rails and only puts in iron, he is not allowed to plead that the manufacturers did not tell him the difference, and that he did not ask. If a jeweller is asked for a fine gold bracelet, and sells one two-thirds alloy, he is not permitted to plead that he had no means of knowing the amount of impurity. Why, then, should a grocer who sells made-up cocoa as pure be allowed to repudiate any obligation to know what he sells. Is it any hardship on him to insist that he shall obtain a warranty from the manufacturer or the merchant? Not at all! for if he is deceived in the article he buys, and is afterwards punished for selling adulterated goods, he has his remedy to the fullest extent against the firm who supplied him.

These arguments must, we believe, recommend themselves to any unbiased mind, and we therefore leave the subject for our readers' consideration, quoting simply the words of the *Pall Mall Gazette*: "It is to be hoped that Conservative reaction will not take the form of undoing the little that has been done for the protection of the public against adulterated food. Such a policy will, no doubt, be greeted with frantic applause by a large number of dishonest and disreputable traders, but it will create a very disagreeable impression in thousands of households where even under the working of the present imperfect machinery of the Adulteration Act, pure milk is now thankfully drunk as a pleasing novelty, and will not be relinquished without a feeling of intense disgust and dissatisfaction?"

Notes on Current Topics.

Professor Humphry on Intemperance.

THE annual report of the Cambridge University Temperance Union contains a speech by Dr. G. M. Humphry, F.R.S. He said there was nothing which tended to sap the foundations of society, physically, morally, and spiritually, so much as intemperance, lying as it did at the root of almost every sin, evil, and crime. With regard to the physical evils resulting from intemperance, he would say that there was nothing which tended more to enervate the body and lower the *physique* of the people of the country, and thus necessarily to lower its moral and religious condition, than the evil of intemperance. They were at present in England considering sanitary questions, but there was no one of the evils they were seeking thus to remedy, he was certain, which was eating, as this was—like a cancer—into the heart of the people. The danger, the terrible destruction, it was producing was incalculable. When a medical man was called to a patient one of the inquiries he made with eagerness and earnestness was whether he was a temperate man or not, feeling that upon this point in a great measure often depended the issues of life and death. He thought this was a peculiarly fitting time when the question should be taken up, because of the increase of wages that was taking place. It was to be feared that increase of wages too often led to increase of drinking. Nowhere was there such a large

pauper element as in England, and that pauper element was due in the main to the fact that we were a drinking people. As a practical mode of meeting the question, he would impress upon all to follow these two maxims:—First, never, under any consideration, should wages be paid in the form of drink; this was a prodigious evil—giving a man a pint of beer for doing a given service. Secondly, never, or scarcely ever, except medicinally, should beer or wines or spirituous liquors be taken in the intervals between meals. This applied to all classes in the community. There was, he believed, nothing worse than for a man, and not less a woman, when feeling low and weak and depressed, as is often the case about eleven o'clock in the day, to resort to the habit of taking a glass to revive them. This occasional, and then frequent, taking of stimulants was at the root of a vast amount of physical evil; and he did not think his own (the medical) profession altogether free from blame, on account of the advice sometimes given incautiously in this respect. He was, therefore, glad of the opportunity of raising his voice against such a terrible mistake.

Falsification of Articles of Household Use.

IF a small quantity of milk of lime be added to melted lard, the soap which is formed permits of the incorporation of about 25 per cent. of water with the fatty body in such a way that at first sight the falsification is not noticed. This property of calcareous soap is known to and put to use by the American lard renderers, as was discovered by a druggist who employed some such lard in the preparation of a pomade containing nitrate of mercury; he was astonished to find his pomade assume a slate colour. On examination, the lard was found to contain much water and some lime.

In the *Boston Journal of Chemistry* we find an article from the pen of Mr. Sharples, the State Assayer. Speaking of the adulteration of soap, he says:—"Other things being equal, the man is most successful in the business who can incorporate the most water in the soap and still have it retain its form. This adulteration can easily be detected by drying it, first at a gentle heat and then at 212° F., having previously reduced the soap to fine shavings.

The next adulteration, and one which has many defenders, is the use of rosin instead of fat in the manufacture of the soap. Some of the most expert at this business have succeeded in thus introducing 75 per cent. of rosin to 25 per cent. of tallow. This, with rosin and sal soda at about 2½ cents per pound, while the soap sells for 5 or 6, yields a reasonable profit. Another common adulterant is finely ground talc or marble dust. These are mere make-weights, and there is no reason for their admixture. I recently heard of a manufacturer who boasted that he had been able to introduce over 65 per cent. of adulteration in his soap, exclusive of the rosin."

Jelly from Old Boots.

THE reader may stare, but science smiles superior and asserts very emphatically that a toothsome delicacy can be made from a dilapidated foot covering. Some time ago, says the *Scientific American*, Dr. Vander Weyde re-

galed some friends not merely with boot jelly, but with shirt coffee, and the repast was pronounced by all partakers excellent. The doctor tells us that he made the jelly by first cleaning the boot, and subsequently boiling it with soda, under a pressure of about two atmospheres. The tannic acid in the leather, combined with salt, made tannate of soda, and the gelatin rose to the top, whence it was removed and dried. From this last, with suitable flavouring material, the jelly was readily concocted. The shirt coffee, incidentally mentioned above, was sweetened with cuff and collar sugar, both coffee and sugar being produced in the same way. The linen (after, of course, washing) was treated with nitric acid, which, acting on the lignite contained in the fibre, produced glucose, or grape sugar. This roasted, made an excellent imitation coffee, which an addition of unroasted glucose readily sweetened.

Circumcision of the Jews.

DR. LEVITS (*All. W. M. Z.*, No. 46, '74) says that circumcision, which is represented as harmless, is dangerous, as he knows from a thirty-five years' practice, which has shown him six cases of death, and over twenty accidents, which have occurred in consequence of the operation. Bleedings sometimes caused by hæmophilie are the causes of death. Losses of blood are common consequences of the operation, and the cause of long-continued weakness. The conveyance of syphilis is greatly aided by the practice, by the old method for stilling the loss of blood, which has been forbidden in France, namely, the taking of the infant's penis into the mouth of the operator and the application to the wound of wine held in the mouth. The conveyance of syphilis by the operator is farther facilitated when several children one after the other are operated on, one of which may have hereditary disease, and a careful cleansing of the instruments, as well as the finger-nail of the operator, does not take place. Ricord draws attention to the last point. As a further disadvantage, the over-early development of the life of the genital apparatus by the uncovering of the glans is mentioned. Erections and emissions are more common and earlier among the circumcised, and the inclination of the Eastern nations to onanism is explained by the want of the prepuce. The hygienic use of circumcision is confined to cases of phymosis, which does not justify the dangerous operation, and he thinks it not true that syphilitic infection is prevented by it. He considers it a severe operation, and dangerous to life, and want of thought is the cause of its being still practised. He appeals to medical men not to sanction the practice by assisting at it, and to advise their patients not to practise it. No one is forced to make use of the practice, and law might prevent it, as being an infringement of the rights which a parent has over his child. The practice of circumcision ought to be cried out against by all scientific medical men.

A Judicial Opinion on Dublin Mortality.

EVEN a Chief Justice commits an indiscretion when he ventures to talk upon a subject of which he has little knowledge, and that indiscretion is the greater because an expression of opinion from him carries weight with it, and is accepted almost as if it were unerring truth. In

charging the jury in a recent case in the Irish Queen's Bench, Chief Justice Whiteside, speaking of certain evictions of tenants from their miserable hovels, said "that leaving the people in some of those dwellings was very often like the philanthropy of an hospital Sunday in Dublin, where the death-rate was 42 as compared with 29 in London—a philanthropy which, he thought, was a sort of inhumanity, for it would be better not to fill the hospitals, and to take precautions instead of cure."

This is a speech evidently calculated to convey an impression that a residence in Dublin was nearly twice as dangerous as in London, and that it was foolish to make an effort in the direction of improved and extended hospital relief, inasmuch as, by so doing, the poor were subjected to greater risks. The fact is that in the week ending January 16th, the period in which the Chief Justice spoke, the deaths registered in Dublin represented an annual death-rate of 43 per 1,000 living, while those registered in London equalled a death-rate of 29 per 1,000 annually. But, to argue from one week's death-rates, and to conclude that they are the average rates, is scarcely logical—it is an *argumentum à particulari ad universale*, of which his lordship would not be guilty in a legal matter. The death-rate of Dublin in the ten years ending 1874 was 26 per 1,000, that of London was about 23 per 1,000; so that, in fact, the risk of residence in Dublin is hardly anything greater than in London.

Spinal Meningitis and Curara.

DR. J. MORF (*Aert. Intell. Bl.*, No. 51, 1874) mentions a case of spinal meningitis occurring in a soldier, aged 22, of good constitution, who, on the 23rd of March, began to complain of stiffness in the joints and difficulty in walking. The joints of the feet were swollen, and rather tender on pressure. On the next day the uneasiness was still greater, the patient was compelled to lie in bed, but in other ways felt quite well. The next day there supervened tetanic spasms suddenly. The whole body began first of all to shake, and the head was thrown back. The skin showed heightened sensibility, but the belly was, above all, sensitive, the spine, and those parts of the body where the spinal nerves were most superficial, as in the axilla and the loins. The slightest touch on these parts caused at once severe spasm.

Morphia was first given in large doses and leeches applied over the belly. The patient fell asleep, and on awaking complained of great pain in the belly, and there was hyperæsthesia of the skin. In the evening spasms returned, and these remitted next morning, and so on for several days. A trial with curara was then made. Six millegrammes were subcutaneously injected thrice a day, and after the third injection the pains ceased, and the patient slept and had no attack next day. These injections were made nearly every day, and the spasms remained absent; but if left aside they returned. In seventeen days the spasms remained absent. He was considered cured, but three weeks afterwards the spasms reappeared, and were treated again with curara with excellent result.

Ether and Chloroform.

DR. LEE, of Chicago, in a paper read before the Cook County Medical Society, says that chloroform is more

generally employed in the United States than ether, it being more agreeable to the taste, more rapid in its action, and requiring less to produce the desired effect. He mentions that of 92,815 ether inhalations there were 4 deaths, or 1 in 23,204; in chloroform 53 deaths to 152,260, or 1 in 2,873. Hence, chloroform is about eight times as dangerous as ether. Many surgeons have, therefore, quite abandoned the use of chloroform as an anæsthetic. Professor Gunn, of Rush Medical College, and Professor Andrews, of Chicago Medical College, have used ether exclusively for years, with accident, he believes. According to Dr. Ashurst and Dr. Morgan, of Dublin, in giving ether air may be safely excluded; with chloroform the greatest care must be taken to admit air. When Morgan's inhaler is used, anæsthesia is producible as rapidly as with chloroform. Dr. Diday, of Lyons, says that any person using chloroform instead of ether is culpable. Lister, of Edinburgh, however, seems greatly to prefer chloroform; but there is hardly a practitioner who has had to use chloroform frequently that cannot call to mind some very narrow escapes. The space between complete insensibility from chloroform and death is short indeed. Under five years of age, however, it seems that chloroform is not dangerous to life. It seems also to do no harm in labour cases. In the north of Ireland ether drinking has come into vogue. The usual quantity of ether taken is from two to four drachms five or six times a day.

We quite agree with Dr. Lee that the use of ether ought to be made a rule of practice instead of chloroform. We have seen and heard of too many deaths from the use of the latter anæsthetic to hesitate any longer in pronouncing that those persons who administer chloroform with the present knowledge of its dangers are culpably careless and ignorant.

Death from Polypus on a Vocal Cord.

DR. MORF also mentions a case of sudden death occurring in a young soldier, æt. 21, who complained of slight difficulty in swallowing. Suddenly difficulty of breathing arose, and the patient became comatose and died. The post-mortem examination showed a large polypus with broad base on the upper aspect of the right vocal cord.

Aneurism Cured by Digital Pressure.

DR. WILLIAM OLDRIGHT (*Canada Lancet*) mentions the case of a gentleman in Toronto who had, on the inner aspect of the right thigh, about the junction of the middle and lower thirds, a large flattened pulsating tumour, about seven inches in its long diameter, or in the course of the vessel, and six in its antero-posterior diameter, appearing to extend both anteriorly and posteriorly to the femoral artery. It was very painful. Pulsations in the dorsum of the right foot and ankle were weaker than those on the opposite side. He decided to tie the femoral, but first thought he would try digital pressure. Twelve gentlemen volunteered their services, and each pair remained on duty four hours. The two on duty relieved each other every ten or twenty minutes, the one maintaining pressure and the other keeping his hand on the tumour so as to detect any inadvertent relaxation. The evacuation of the bowels was secured before commencing, and opiates were then given to control the action of the bowels, and

relieve pain during the time occupied by the pressure. This was commenced on December 2nd, at 9 p.m., and continued until the afternoon of the 4th. He thinks that pulsation in the tumour had stopped in thirty-eight hours. During the pressure, the tumour was very hot, and more tender than before. This state of things disappeared in a day or two. The clotted vessel could be felt for a couple of inches or so above the tumour, and vertically across the upper part of it. The edge also appeared hardened. On each side of the occluded vessel fluctuating vessels could be felt, from which one would be inclined to argue that the vessel had originally given way posteriorly. The patient (in January 21, 1875) was walking about. During pressure, which was without intermission, the operator's nails were carefully attended to, and they were directed only to press hard enough to stop pulsation. There was no abrasion of the skin.

New Books in Medicine, Surgery, and Science.

Cremation.

It appears that the Council of the Cremation Society is alive and doing, and are now approaching the question in a practical way. They have, we learn, purchased a piece of ground for the erection of a building in which the religious rites can be performed prior to the incinerating process. The estimated cost of the proposed building is £3,500, towards which £1000 has been promised.

Trichinosis.

In "Ziemssen's Cyclopædia of Practical Medicine," 1874, some points connected with trichinosis are carefully summed up by Dr. Heller.

Diagnosis.—When the disease is met with in single cases, it is often very difficult to recognise. In severe cases diarrhoea is almost always present, with slight fever, or perspiration. Muscular paralysis is one of the most well-marked symptoms. It is distinguished from cholera by the sweating. The onset of œdema of the face on the seventh day is a strong proof of the presence of the disease. The urine in trichinosis has no albumen. After this there is marked general prostration, and violent muscular symptoms, dyspnoea, hoarseness, bronchial catarrh, and sleeplessness. Excision of a piece of muscle shows the trichinæ in the microscope.

Prognosis.—The less sufficiently the meat is prepared and heated when eaten, the severer is the sickness. Raw minced meat, as eaten in Saxony, is the most dangerous of all, and has caused epidemics of the disease. A long-continued diarrhoea gives an unfavourable prognosis. Coma, delirium, and sopor are all of bad augury. Children generally recover.

Treatment.—The object of treatment is first to kill the intestinal trichinæ. No remedy has been found which will kill the trichinæ and be harmless to man. Purges are not so useful as it has been expected. Calomel purges, however, are recommended. The occurrence of bed-sores is to be prevented by large india-rubber water-pillows.

The blood after death is found to be with difficulty

coagulable. Effusions are found in the pericardium and pleural cavities. Putrefaction soon sets in. The mesenteric glands are often found swollen to a soft pulp. The liver becomes fatty. Fattiness of kidneys and heart has been seen in some cases. Changes in the muscles are visible by the naked eye in the end of fifth week, and only in severe cases; these are greyish streaks running in a longitudinal direction along the muscles. In the tenth week the muscles are shrunk and pale. The trichinæ are usually most numerous in the diaphragm, the intercostal muscles, those of the neck and larynx, more infrequently in those of the extremities. The muscles of the eye are not unfrequently attacked. The muscle in the neighbourhood of the trichinæ loses its transverse and longitudinal striae. Simple fatty degeneration sets in in many other bundles, and the waxy degeneration of the muscle takes place.

Quinine in Menorrhagia.

DR. BARTHAREZ (*Abeille Méd.*, 21 Dec.) mentions a case where uterine hæmorrhage, having resisted ergot of rye, prescribed first of all, but which had only produced a slight lessening of the flow, was much benefited by quinine.

For another case, one dose of quinine cured a menorrhagia with symptoms of uterine congestion and febrile reaction. Dr. de Mussy mentions the case of a lady affected with knotty rheumatism, who was subject to uterine hæmorrhages of considerable violence, which had made her very bloodless. These attacks occurred at menstrual times. After uselessly trying different remedies to lessen the violence of the attacks, Dr. de Mussy prescribed pills composed of 15 centigrammes of disulphate of quinine and 10 centigrammes of extract of cinchona flower, of which she took from 8 to 10 a day. For the first time the menstruation lost its hæmorrhagic character and the duration became normal.

Plaster of Paris Bandage.

DR. WACKERHEGEN (*New York Medical Journal*) says that, as he has often experienced considerable difficulty in removing plaster of Paris dressings, when applied by the roller bandage, and especially when obliged to remove them on account of pain caused by an increase of the swelling, he submits the following plan: Having procured a woollen or cotton stocking sufficiently long to reach to the knee-joint, he cuts from it, as a pattern, six layers of coarse red flannel, one quarter of an inch larger, to allow for shrinking. The flannel is soaked in water, pressed, and laid over the back of a chair, ready for use. A one-quarter-inch cotton rope is now sewed to the posterior median line of the stocking. The plaster of Paris being in process of preparation, the stocking is cut in the anterior median line, applied to the fractured limb, and laced up in front, including the rope, extension and counter-extension being kept up by assistants, and the fracture adjusted. Each layer of the flannel is now separately saturated in the plaster paste, and applied, three layers to each side of the limb, being careful to avoid covering the rope. After this, a layer of plaster paste is applied to the flannel, and when this has become sufficiently dry, a coating of shellac varnish is applied,

producing an elegant finish, and also giving firmness to the splints. This dries in about fifteen minutes. This dressing can be removed in from three to fifteen minutes, by loosening the rope from the plaster and cutting the thread which binds it to the stocking. The rope having been removed, the plain stocking surface can be cut through with an ordinary pair of scissors. The splint is then removed in two lateral portions, each half of the stocking remaining attached to its corresponding splint.

On the Dissipation of Energy.

ON Friday evening last, at the Royal Institution, Lord Rayleigh gave a most interesting lecture on the above subject. He remarked that one theory of thermo-mechanics is well known—the conservation of energy—but another, the dissipation of energy, is not popularly understood. That work done is convertible into heat is universally understood, but the reverse is the case when the question is asked, is heat convertible into work—that is, direct, without the intervention of any mechanical engine. The assumed law of the dissipation of energy was promulgated by Carnot, and it has been demonstrated that to convert heat into work there must be two temperatures, and that it is no more possible to convert heat into work without a difference of temperature than it is to drive a water-mill without a fall of water. The difference of work is equal to the difference of temperature. Clausius laid down the theory that it was impossible for heat of itself to go from a lower to a higher body; but by mechanical intervention this may be done, as in the freezing machines. In chemical operations—distillations, for example—consecutive falls of temperature might be utilised directly by very finely graduated series. In conclusion, the lecturer took the gloomy view that in creation there existed a constant dissipation of energy which would ultimately reduce all the existing matter in space to torpor and stagnation.

DR. LIONEL BEALE will lecture at the Royal College of Physicians of London "On Life and on Vital Action in Health and Disease" on March 12th, 17th, and 19th, at 5 o'clock.

THE Worshipful Company of Mercers have made a grant of fifty guineas and an annual subscription of ten guineas in aid of the funds of the Royal National Hospital for Consumption, Ventnor, Isle of Wight.

A PUBLIC meeting of the London Hospital Sunday Fund Council was held in the Egyptian Hall of the Mansion House last Monday, to receive the report of the Special Committee appointed at the public meeting on the 4th January last, and to determine the system of distribution for the year 1875.

FURTHER proof of the practice of cremation in England by the ancients was adduced on Saturday last. When some of the employés of the Great Eastern Railway were making excavations near Fulbourn Station they came across the remains of an ancient furnace which contained the calcined remains of several bodies.

At the Salford Borough Court, on Saturday, Elizabeth Marsden, a midwife, living at Pendleton, was charged on remand with the manslaughter of Mary Ellen Goodier, and of Mrs. Ann Mills. Mr. J. A. White, surgeon, Broad Street, Pendleton, was called, and after his evidence the prisoner was committed to take her trial at the assizes upon both charges.

DR. JOHN EDWARD GRAY, the celebrated naturalist and ornithologist of the British Museum, died on Sunday morning, at the age of 75. The deceased had resigned his official appointment, and was about to retire into private life, when death suddenly deprived the world of one of the most scientific men in his department the present generation has seen.

THE Medical Society of the Dublin College of Physicians will meet this evening, at 8 o'clock, in the College Hall, when the following communications are set down for reading:—Dr. Grimshaw on "a Case presenting Cataleptic Symptoms;" Dr. James Little on "The Treatment of Scarlatina;" Dr. A. W. Foot, "Notes on Scarlatina."

THE Dublin Obstetrical Society met on Saturday last, at the College of Physicians, when the following communications were read:—Dr. Denham on "A Case of Extra-Uterine Fœtation;" Dr. Nicolls (Longford) on "Protracted Labour, Hour-glass Contraction, Hæmorrhage, and the Introduction of the Hand into the Uterus;" Dr. MacSwiney "Report of a Case in Midwifery Practice."

THE guardians of Coleraine Union have resolved to exercise the powers vested in them by the Public Health Act to obtain a pure water supply for the inhabitants of Portrush. The proposed waterworks, it is estimated, will cost £3,520. The clerk of the union was directed to write to the Local Government Board to ascertain upon what terms a loan to execute the works could be obtained.

THE science of medicine and surgery according to European notions is making some progress in Japan. In the hospital at Hakodadi there are twenty young men regularly entered as students of medicine, daily lectures are given, and "bedside and other clinical demonstrations," the curriculum being similar to that of most medical schools. An illustrated medical journal in the Japanese language is also published every two months.

AROLD'S FERRUGINOUS WINE, WITH CINCHONINE AND ALL THE SOLUBLE NUTRITIOUS QUALITIES OF FLESH.

THIS preparation, which has recently been introduced to the notice of the profession and the public of this country by the same house as Rigollot's mustard leaves, brings with it a high Continental repute. As, however, a mere opinion is of little value as to the merits or demerits of any medicament or dietetic, we have submitted this, according to our usual plan, to a careful analysis, with the following result:—

Proof spirit	20.5 per cent.
Extractive	84.62

	Grains per fluid oz.
Containing saccharine matter, &c. ...	54.2
Nitrogenous extract	21.2
Ash	4.79
Acidity calculated as tartaric acid ...	5.60
Ferric oxide	2.00

This wine is what it purports to be—a ferruginous wine, apparently made with port wine. It contains some cinchona, but this alkaloid is present in small quantities. The iron is held in solution by citric, or tartaric acid, and cannot be precipitated until the organic acids are destroyed by ignition. If such a preparation be thought desirable by the physician, it may be prescribed with perfect safety, as it contains nothing that is deleterious, and is really palatable. Its sustaining and tonic powers must be very considerable, whilst the iron seems present in an assimilable form.

Literature.

CHOLERA: HOW TO PREVENT AND RESIST IT. (a)

THE scope of this work is not fully expressed in the title, for it contains a popular exposition of the best rules of hygiene, which are applicable to all times, but should especially be observed in periods of epidemics.

Professor von Pettenkofer's views are not so well known in this country as they deserve to be, and we have often been amused at the mistakes about them made by medical men generally well informed. Such errors will henceforth be inexcusable, for Dr. Hime has given the clearest possible explanation. The learned professor lately issued a popular work, embodying the results of his investigations into cholera and typhoid fever. We need not say that his researches are acknowledged everywhere to be of the highest importance. They have lately received the emphatic approval of the International Sanitary Congress at Vienna, the proceedings of which are epitomised in an appendix to the volume before us.

From Pettenkofer's numerous writings, Dr. Hime has wisely selected for translation the popular work to which we have referred, and so well has he executed his task that there is not a single sign that the work is a translation at all. Nevertheless, that it faithfully represents the original is attested by the approval of the author, to whom the translator submitted the proof sheets.

Dr. Hime has prefixed to his translation a lucid exposition of Pettenkofer's investigations as to the connection between epidemics and the rise and fall of the ground water. No one who reads this essay can fail to grasp the theory, and its importance is unquestionable. There are few medical works which we wish to see circulated amongst the general public, but this is certainly one. Everyone who takes interest in sanitary matters, everyone who wishes to preserve his own health or that of his family, and to know the best way of avoiding typhoid fever, cholera, and other diseases, should make himself acquainted with its contents, and the public journals of this country might well call attention to it.

COMMENTARY ON THE BRITISH PHARMACOPEIA. (b)

THE British Pharmacopœia is, without doubt, an extremely useful book; but to the busy practitioner or the

(a) "Cholera: How to Prevent and Resist It." By Professor von Pettenkofer. Translated from the German by T. Whiteside Hime, A.B., M.B., and revised by Professor Pettenkofer. London: Baillière, Tindall, and Cox. 1875.

(b) "Commentary on the British Pharmacopœia." By Walter G. Smith, M.D., Dublin, Fellow of the King and Queen's College of Physicians in Ireland, Assistant-Physician to the Adelaide Hospital. London: Smith, Elder, and Co.,

often over-worked student in the search of knowledge, the matter contained in its pages must at times appear dry reading, as in that work they are only furnished with the bare details concerning the various drugs and preparations by means of which they are to endeavour to combat disease; therefore we doubt not they will hail with pleasure the comprehensive and able work which Dr. Walter G. Smith has recently laid before his medical brethren; and we are sure he especially deserves our thanks for the careful manner in which he has avoided giving us merely a *rechauffé* of facts already recorded in the work upon which he comments. By the adoption of this plan, and the omitting of needless reference to botanical minutiae of exotics, Dr. Smith has been enabled to keep the size of his book within reasonable limits, and has also gained much space to insert various highly valuable original remarks, and to call attention to the recent labours of many leading therapeutists, thus considerably enhancing the value of his work. Thus, for instance, at page 150, he lays before his readers in a concise manner the origin and characters of belladonna, condensing his remarks on these points into four paragraphs. Then he passes on to detail at more length the medicinal uses of this drug, and pays due tribute to the labours of Drs. Crum Brown, Fraser, John Harley, M. Costesé, &c., to whom we owe so much of our knowledge of this valuable agent.

Fully appreciating the value of an exact knowledge of the physical and chemical properties of drugs, the author has not neglected pointing out the characters and tests of various articles, and the modes of detecting adulterations. At the same time attention is drawn to the chemical relations and therapeutic use of each metal, and chemical equations are expressed in the modern notation, a mode of explanation at once exact and concise.

Thus, at page 355, the compounds of mercury are divided into four classes, viz. :—

Class I. Metallic; Class II. Oxides; Class III. Non-oxygenated (haloid) Salts; Class IV. Oxy Salts. The first class includes mercury and the various preparations which contain this metal, as unguentum hydrargyri, &c. In class ii. we have the black, yellow, and red oxides of mercury with the lotions and ointment prepared from these oxides. Class iii. is composed of mercuric iodide, perchloride, subchloride, and ammonio-chloride, and the various preparations made therefrom; while in class iv. the mercuric nitrate and sulphate is included. By treating the subject in this manner, the author enables his readers at a glance to ascertain the various preparations of mercury, and their chemical composition, thus saving them the necessity of wading through paragraphs of desultory explanation so commonly met with in many manuals. The origin, characters, and chemical relations of this metal are dealt with in a concise manner; and four and a half pages are devoted to an able summary of the general therapeutic effects of mercury and its preparations.

One peculiarity which at once attracts notice in this work, and which is worthy of all commendation, is the introduction under each of the principal metals of a pedigree or genealogical table of its preparations, thus exhibiting their mutual relations at a glance.

Thus, at page 314, on referring to the table, we observe that the various preparations of iron are prepared from iron wire, the sulphate, the persulphate, or the peroxide. This excellent and original mode of arranging the preparations is eminently characteristic of the author, and the student will fully appreciate its value, being thus enabled to learn his chemistry and *materia medica* from the same source.

The various remarks upon the physiological action and the therapeutic uses of each article, although necessarily limited, are yet very good, our attention being paid to recent therapeutic discoveries, and the common error of simply transcribing statements from former works has been carefully avoided; in fact, this work may be considered as being fully *en rapport* with the views of the present day.

Thus, at page 68, attention is directed to the marvellous power aconite possesses over inflammations, especially in the early stages; and at page 153 the value of belladonna in neuralgia, whooping-cough, asthma, epilepsy, constipation, incontinence of urine, &c., is duly noted. It would have been as well if the author had at the same time remarked upon the value of atropia in the treatment of derangements of the sympathetic nervous system, pneumonia, enteric fever, typhus fever, and nephritis, as pointed out by Dr. John Harley and others, and as yet not generally known; but, of course, we cannot expect any great stress to be laid on therapeutics in a work which only proposes to be a Commentary on the British Pharmacopœia. Chloroform, cinchona, belladonna, and opium, are treated at greater length than the other articles, as being more important; and the various authorities who have experimented with these drugs are duly quoted.

In conclusion, we can confidently recommend this work as well worthy of reference, and as a valuable addition to any medical man's or student's library. The publishers deserve praise for the creditable manner in which they have produced the book.

SERMONS FOR THE INSANE. (a)

WHEN last year volume i. of this series of original discourses was issued from the press, we are told by its accomplished editor that it was by way of experiment only. As "necessity is the parent of invention," so he had found the great need of such a work in his capacity as head of a large lunatic establishment, and hoped that those similarly placed, whether as chaplains or superintendents of asylums, hospitals, workhouses, &c., would in like manner find the work of use to them, and appreciate his labours in its production. The object was perfectly legitimate and well planned, and the venture having met with so encouraging a success, volume ii. appears before us as the result. Of course, we cannot be expected in our medical capacity to pronounce an opinion upon the relative value of sermons; sufficient testimony is to be found in the demand for a second volume, which we trust will be as widely circulated as its predecessor. We certainly think that some of our prosy three-quarters-of-an-hour parsons might take a hint from the compilers of "Sermons for the Insane," who all have rightly concluded that a fifteen-minutes' discourse is enough for mortal man to swallow at one dose.

ST. BARTHOLOMEW'S HOSPITAL REPORTS. (b)

THIS volume is the first of the second series, but for convenience of reference is very properly numbered *ten*, the first series having consisted of nine volumes. It is more bulky than its predecessors, and has, we are glad to say, been bound in cloth. If the edges had also been cut the mechanical execution of the book would have been perfect. In this volume are included statistical tables of the patients under treatment in the hospital during the year 1873. In reference to these it occurs to us that a question has lately been mooted as to the expense of the statistical reports of our hospitals with respect to the requisitions of the Committee of Distribution of the Hospital Sunday Fund. Anything which prevented the publication of such reports would be much regretted, and those hospitals which issue volumes of this kind do well, we think, to include them.

The volume opens with an appreciative memoir of the late Thomas Wormald, which will be read by his numerous pupils with the greatest interest. We have ourselves perused it with personal interest, as we compared it with our recollections of his presence. After this we have thirty-two distinct essays on various subjects. Amongst these we have been particularly interested in one by Dr. Tuckwell, on "Clotting of the Blood in Chlorosis." It consists of some carefully recorded cases, which we think will contribute to a better understanding of phenomena that now and then occur in practice. The same author also writes on "Acute Yellow Atrophy of the Liver in Children."

Sir James Paget, in a brief paper on "Disease of the Mammary Areola preceding Cancer of the Mammary Gland," shows how carefully he observes the numerous cases which his great reputation brings him in private practice, and offers a suggestion as to the connection between these two diseases. Doubtless the point will commend itself to the careful observation of general practitioners, who naturally would be most likely to have the opportunity of noticing the relation between what for convenience we may term *ad interim* the two stages.

Dr. Andrew contributes two papers on rheumatic fever. The first gives a number of cases with high temperature; the second is on treatment by a non-nitrogenous diet. It will be remembered that last year Professor Parkes drew attention to the effects of an absolutely non-nitrogenous diet. It occurred to ourselves at the time that such a diet would prove more efficacious than drugs in acute rheumatism, but we had only limited opportunities of trying it. We are therefore pleased to observe that Dr. Andrew formed the same opinion, and has fairly tried the method in the wards of St. Bartholomew's Hospital. He records eight cases, and the general success has been such that he intends to continue the practice, and he expresses his belief that the observance of such a diet promises better results than any other treatment of rheumatic fever. With characteristic caution he notes, however, that it is in acute attacks in young patients whose powers of nutrition are unbroken that it may be used with most confidence; whilst in persons of worn-out constitution, or in those exhausted by long illness, or in whom cardiac or nervous complications exist, it is only to be tried very cautiously, and discontinued unless immediate benefit result. It is also inadmissible in cases of rheumatism with hyperpyrexia.

Dr. Hollis, in a paper on "The Therapeutic Action of Vesicants," relates some interesting experiments which he has carried out, and the conclusion from which he thus states:

1. That their local action consists in first diminishing, and subsequently in destroying the vitality of the parts with which they are brought into contact.
2. That this action is also depletory; whilst increasing the amount of blood in the tissues immediately under the blistered surface, it renders the deeper subjacent structures very anæmic.
3. That, besides the depletory action, blisters influence the system generally, depressing the heart's action, slowing the blood stream, and cooling the temperature of the body. These results are probably due to the reflex action of the central nervous system.

From all this Dr. Hollis concludes that probably many, if not all, the therapeutic advantages of blisters may be obtained from less powerful epispastics; moreover, that blisters injudiciously applied may induce the evil we wish to prevent.

Space prevents us from entering upon the other essays; but we hope on a future occasion to transfer to our columns some of the interesting cases in which they abound.

(a) "Cheerful Words:" Vol. II. of "Sermons for the Insane." Edited by W. Hyslop, of the Church Stretton Private Lunatic Asylum. Pp. 304. London: Baillière, Tindall, and Cox. 1875.

(b) "St. Bartholomew's Hospital Reports." Vol. X. Edited by James Andrew, M.D., and Thomas Smith, [F.R.C.S. London: Smith, Elder, and Co. 1874.

LECTURES ON SKIN DISEASES. (a).

DR. MAPOTHER'S preface will best explain the design and nature of his work. He states: "Three of these lectures formed part of the clinical course in the session 1871-72. They were published in the MEDICAL PRESS, and reprinted at the urgent request of some pupils who heard them. Considerably altered and enlarged, they, with three others lately delivered, compose this little volume, which, be it remembered, does not claim to be a special treatise on skin diseases. Descriptions of the eruptive fevers of the rarer and of the foreign cutaneous maladies, the oft-repeated chapter on the normal skin (which teaches nothing even to a senior student), and the specific formulary, have therefore been omitted."

We might select a number of good and practical hints from the pages of this little volume to illustrate those distinctive features which appear to us to constitute its special value and chief recommendation. Dr. Mapother, when writing about the treatment of chloasma, says: "The cure is very easy, when the patches are washed well with common soap to remove the oily and sweaty matters; a wash of 1 oz. of hyposulphite of soda to 12 ozs. of water is very effectual. Weak sulphur ointment acts fairly. Mr. Rivington accidentally discovered that a solution of cyanide of potassium, 5 grains to the ounce, such as photographers use, will quickly kill the fungus. I have often verified the statement, and would always use the remedy, except that such caution is needed owing to its terribly poisonous character."

Most persons who have had the opportunity of studying and treating a series of cases of eczema, that very common and varying form of cutaneous eruption, which in its severe and aggravated condition is no doubt a formidable and troublesome disease, would, we fancy, be disposed to coincide with the views entertained by Erasmus Wilson, Fox, and others who "tell us that eczema is a disease of debility," a conclusion which Dr. Mapother evidently does not fully accept. Thus he says: "I know of one case of highly inflammatory general eczema recurring yearly, when bleeding from the arm alone gives relief." Such a case is surely exceptional, for out of a very large number of persons suffering from eczema the reviewer can assert that he has never yet observed a parallel one; and a careful retrospect of all the results of his past experience induces him to believe that attacks of eczema demanding any degree of depletion beyond occasional mild purgatives are truly rare, at least in private practice and in the better classes; he would also venture to say that his estimate of the value of sulphur and sulphurous waters as remedial agents is very different from that which Dr. Mapother has been led to adopt.

The treatment of onychia topically by applying to the ulcerated surface pulverised nitrate of lead is referred to by Dr. Mapother in most favourable terms. No doubt it is a mode of treatment deserving the highest commendation and one that seldom if ever fails to cure if properly carried out. Whatever be the reason for it, onychia appears to have been unusually prevalent in Dublin during the past year, and in no case where either the powdered salt or a strong solution was used did it fail us in producing a perfect recovery.

We marked several portions of this work for comment and commendation. Its special value is that it presents freely and without decorative ornamentation the results of careful study and intelligent reflection based on an extensive series of cutaneous diseases. There are few who are devoted to such pursuits who may not expect to arrive at results which differ in minor points from their fellow-observers; but none can labour with earnestness and perseverance without being able to contribute more or less to the common fund of medical knowledge and assisting to advance the successful treating of disease. Dr. Mapother's work is like most of those proceeding from

our Dublin school—essentially practical—and does credit to his powers of observation and teaching. We cordially recommend it to all students and practitioners as well worthy of their considerate and attentive perusal.

LECTURES ON PUBLIC HEALTH. (a)

In the spring of 1873 the Royal Dublin Society invoked the assistance of the Dublin Sanitary Association to aid in the delivery of a series of Lectures on Public Health. Owing to unforeseen circumstances the publication of the useful volume now under notice was delayed, and a like fate from like causes awaited its notice in our pages.

The course numbered ten lectures: the first, an introductory one, on the "Growth of Sanitary Science, and its Progress in Ireland," was by Dr. Wm. Stokes, Regius Professor of Physic in the Dublin University. It is hardly necessary to say that the distinguished professor dwelt upon several matters connected with this subject with that ability which has rendered his name so well known wherever medical science is cultivated.

The fact that Dublin, with many natural advantages, is far in the rear of other cities not so favourably placed in its vital condition, and calls for renewed energy on our part, was forcibly shown by Dr. Stokes. He dwelt on our difficulties, the poverty and ignorance of so many members of the lower classes in Dublin, and he asked for greater activity on the part of the local authorities as well as of individuals.

We cannot here indicate the many important subjects treated by the several accomplished men who succeeded the Regius Professor in the several lectures; it must suffice to say that Dr. Reynolds lectured upon the "Discrimination of Good Water and Wholesome Food," illustrating his subject by several interesting experiments.

Dr. J. W. Moore pointed out the bearing of Meteorology on Health and Disease, explaining the change which years have effected in the meaning of the word, which now refers rather to weather, climate, and many terrestrial phenomena than to astronomical science. The important connection that has been observed between the weather and many diseases, as illustrated by well authenticated records at home and abroad, must be borne in mind by medical men and sanitarians everywhere.

"The Geographical Distribution of Disease as illustrated by Beri-beri, Yellow Fever, Cholera, and other Diseases," was treated of by Dr. James Little, who gave a clear and intelligible explanation of the terms zymotic, diathetic, &c.

Dr. Grimshaw also treated of "Zymotic Diseases," coupling the subject with those now termed preventable Maps, diagrams, &c., were used in illustration of this and other lectures.

Dr. Hudson treated his subject, "Liability to Disease," with his well-known ability.

Dr. MacDonnell mentioned several interesting matters in connection with the diffusion of possible germs of disease in his discourse on "Antiseptics and Disinfection."

Dr. Mapother's subject was the important one of "Artisans' Diseases." Mr. Henderson, on the "Construction of Dwellings with a view to their Sanitary Arrangements," and Mr. Furlong, on "Sanitary Legislation," completed the series of popular lectures, which justly attracted a highly respectable and intelligent auditory, and served not a little to advance the cause of sanitary science in Ireland. Since that time the Irish Public Health Act has come into force, and from it we trust good results may arise, notwithstanding some opposition which has already been set up against it. We congra-

tulate the Dublin Society and all who were engaged in the work which we have been considering on the production of a creditable, useful, and interesting volume.

Medical Affairs in Parliament.

THE MEDICAL ACT, 1858.

On Thursday last, Mr. A. MILLS asked the Vice-President of the Council whether, under the authority conferred by the Medical Act, 1858 (21 and 22 Vic., cap. 90), it was in the power of the Privy Council to establish one uniform test of efficiency for all medical practitioners in the United Kingdom, or whether further legislation would be required in order to effect that object.

Lord SANDON, in reply, begged to state that the Privy Council has not the power of enforcing a uniform test. It may, however, if set in motion by the General Council of Medical Education, take measures for securing that none of the existing bodies empowered to grant certificates shall do so without securing a proper standard among the candidates, by the process of refusing registration to the candidates certificated by any examining body in default.

ADULTERATION OF BEER.

Mr. SCLATER-BOOTH informed Mr. Pemberton that he proposed going into committee *pro forma* on the Adulteration of Food Bill that evening, with a view to introduce certain amendments. His hon. friend would find on reading the bill that it provided for everything which was provided for in the adulteration clauses of the Licensing Act of 1872. Those clauses were omitted by his right hon. friend (Mr. Cross) in the Licensing Bill which passed last year, as it appeared for the satisfaction of all parties that the adulteration of beer should be dealt with under a general law. Therefore, it was not intended by the Government to introduce any special provision in the Adulteration of Food Bill with respect to the adulteration of beer.

UNINHABITABLE HOUSES AND CONTAGIOUS DISEASES.

Replying to Sir L. Palk, Mr. SCLATER-BOOTH said that, under various acts, there were powers which enabled local authorities to require the removal or reconstruction of houses unfit for habitation, but such a power did not rest with the Local Government Board. With regard to hospitals for contagious diseases, the urban sanitary authorities and the local boards had power to provide them, but the Local Government Board had no such power.

MIDWIFERY PRACTICE.

Mr. SCLATER-BOOTH, in reply to a question respecting the trial of the midwife named Elizabeth Ingram, said it appeared that she was acquitted on the ground of ignorance, and therefore it was to be inferred that she might have been convicted under the existing law. Such matters had frequently been under the consideration of the Local Government Board, and there had recently been a correspondence between himself and the Home Secretary in reference to cases at Leicester and Wolverhampton. The whole subject was at the present time under the consideration of government.

On Friday the House of Commons went into committee of supply, when the following votes were agreed to:—£352 for the office of registrar of births in Scotland; £340 for the office of registrar of births in Ireland; £1,504 for the Local Government Board in Ireland.

Correspondence.

DUBLIN HOSPITALS AND PROVINCIAL SURGEONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Permit me to call attention to the great injustice which is inflicted on provincial surgeons, and indeed on the Dublin men themselves, by the present lax system of admission to the Dublin hospitals. Every other day well-to-do country patients find their way into those institutions. This is especially true of the religious hospitals, such as the Mater Misericordie, &c. &c., where the double system of admission by the staff and by the religious managers tenfold increases the facilities for abuse. The following is the usual process:—Some rural philanthropist who wishes to exhibit a little cheap benevolence at the expense of the medical faculty, and who perhaps contributes a pound to the charity, writes up to the reverend mother or to the manager, or to Doctor So-and-so, and recommends Peter Barlow or Mary Blake as a poor deserving person sadly in need of medical skill, and entirely unable to pay for it. If there be room, or if the case be interesting, the party is admitted at once, and it is only when he dies or leaves the truth leaks out—oftener it never comes out—and the party is found to have been better able to pay for advice than the surgeon or physician to give it gratuitously. Not long ago I found it my interest to perform lithotomy for a fee which I subsequently found was the sum which the parents calculated it would cost them to stay at an hotel in Dublin while their child would be receiving gratuitous treatment in some Dublin hospital. The Dublin members of the profession are as much interested as any country practitioner in checking this great abuse; nor would the remedy be a very difficult one. They would only have to make it a rule to admit no one to hospital without first communicating with two anonymous local practitioners as to the circumstances of the party seeking admission.

I am, dear Sir, yours faithfully,

Cashel, Feb. 23.

THOMAS LAFFAN.

Medical News.

London Hospital Sunday Fund.—A large meeting was held on Monday at the Mansion House, the Lord Mayor presiding. It could not be said that harmony prevailed in the deliberations, but after a stormy scene, the following motion by Dr. Morell Mackenzie was carried and the meeting adjourned after the usual plastering ceremonies were gone through:—“1. The committee consisting of nine members, and the Lord Mayor as president *ex officio*, shall be elected at the first meeting of the council after the annual public meeting. 2. No person holding office in a hospital or dispensary, whether it participates or not in the Hospital Sunday Fund, shall be eligible to serve on the committee. This rule shall not apply to patrons, presidents, vice-presidents, or governors as such. 3. The system of distribution shall be primarily based on the last three years' expenditure of each institution, after deducting from that amount a sum equal to the income derived from endowments, realised property, and legacies exceeding £100, but under no circumstances shall the contributions of patients be deducted from the basis of the award. 4. In all cases where the general expenses of management exceed 20 per cent. of the annual subscriptions and donations (not including the donations from the Hospital Sunday Fund), such excess shall be deducted from the primary basis of award, but in no case shall the primary basis of any institution be lowered, or any award withheld, until after a conference has been requested with the managers of the particular institution concerned. 5. Although no award shall be made on account of money collected for building funds or endowment funds, cost of management to the extent of 20 per cent. shall be allowed in connection with such funds, and the management expenses thus incurred shall be deducted before the general expenses of management are computed. 6. Special hospitals are entitled to participate in the fund on the same basis as general hospitals. 7. Incurable hospitals are entitled to participate

in the fund on the same basis as general hospitals, but the basis shall be limited to the expenditure in connection with patients treated within the walls of such institutions. 8. That it be an instruction to the committee of distribution to place dispensaries on the same footing as hospitals as regards the general basis of award, and that only such dispensaries as are managed by a committee duly constituted be admitted to participate in the fund."

NOTICES TO CORRESPONDENTS.

DR. EDWARDS.—We thank you for the excellent suggestions, and shall be glad to have your "Recollections of Medicine in America" as soon as your time permits. It is quite true that there are enormous obstacles to sanitary reform arising from drink and over-population. The latter point, as you say, is a most unpopular one to allude to.

DR. W. S. will find his inquiry answered in the present number. MR. SWAYNE had best consult a duly qualified practitioner in his town. The individual named is a quack of the worst type, and has been convicted under another name.

MR. SARGANT is thanked.

PROF. RUSKIN.—We bear it stated on authority that the learned Professor, having narrowly escaped the Shipton railway accident, now travels by road. A recent journey of not very many miles is said to have cost him £70 for special conveyances.

DR. S. E. N.—The work has been out of print for many years. Your only certain chance of seeing it is in the Library of the British Museum.

DR. A. H.—We could not possibly accept the communication for our columns in its present form.

DR. W. C. Notts.—The report has been received.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly inform me through your correspondence columns where I can obtain the papers of the past Preliminary (Art.) Examination of the Apothecaries' Hall, London,

And oblige, yours truly,

J. G. W. HAYES.

[Previous Arts Examinations can be obtained on applying to the Secretary at the Hall.—Ed.]

THE SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—The numerous appeals which are made from time to time to medical men on behalf of the widows and orphans of their deceased professional brethren make us anxious to draw your attention to the advantages offered to medical practitioners residing within the London district and in Middlesex by the Society for the Relief of Widows and Orphans of Medical Men. This Society, instituted in the year 1788, has now an accumulated capital amounting to more than £70,000, the interest on which, together with the subscriptions of members and donations, is distributed in grants to those widows and orphans of members deceased who have been left unprovided for. At the present time there are 68 widows and 20 children receiving annual grants from the Society, which last year amounted to £2,930 10s., and in this manner £29,761 3s. 6d. have been distributed since the formation of the Society.

The Secretary attends at the office, 53 Berners Street, Oxford Street, every Wednesday and Friday from 4 to 5 p.m., and from him may be obtained copies of the laws, lists of members, and forms of proposal for membership. He will also give any information required.

We are, Sir, yours truly,

GEORGE BURROWS, President.

JAMES T. WARR,

WILLIAM FULLER,

RICHARD QUAIN, M.D., } Treasurers.

JOS. B. BLACKETT, Secretary.

Berners Street, March 3rd, 1877.

LUNN ON "THE PHILOSOPHY OF VOICE."

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Referring to the notice of my book in your last, I beg publicly to express my regret that Dr. Prosser James's disclaimer did not come before me until my work was in the binder's hands. The error will be corrected in the second edition, shortly to be issued.

I am, Sir, yours truly,

CHARLES LUNN.

MEETINGS OF THE LONDON SOCIETIES.

WEDNESDAY, March 10th.—Royal College of Surgeons, 4 p.m. Prof. W. K. Parker, "On the Structure and Development of the Skull."

ROYAL COLLEGE OF PHYSICIANS.—5 p.m. Dr. Greenhow, "On Addison's Disease."

HUNTERIAN SOCIETY, 7½ p.m. Council Meeting. 8 p.m. Mr. D. De Berdt Hovell will introduce a discussion on "Ventilation in the Treatment of Scarlatina."

EPIDEMIOLOGICAL SOCIETY, 8 p.m. Dr. Geo. H. Evans, "On Arithmetical Questions involved in the Rise and Progress of Epidemics."

THURSDAY, March 11th.—ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, "On Electricity."

FRIDAY, March 12th.—Royal College of Surgeons, 4 p.m. Prof. W. K. Parker, "On the Structure and Development of the Skull."

ROYAL COLLEGE OF PHYSICIANS, 5 p.m. Dr. Beale, "On Life, and on Vital Action in Health and Disease."

ROYAL INSTITUTION, 8 p.m. Weekly Evening Meeting. 9 p.m. Prof. Abel, "On Accidental Explosions."

CLINICAL SOCIETY, 8½ p.m. Dr. T. T. Whipple, "Fatal Pleuro-pneumonia in an Opium-eater." Mr. Barwell, "On a Case of Acute Necrosis in which the whole Shaft of the Uterus was removed." Dr. Thos. Dowse, "On an unusual Case of Lead-poisoning."

SATURDAY, March 13th.—Royal Institution, 3 p.m. Prof. W. K. Clifford, "On the General Features of the History of Science."

MONDAY, March 15th.—Medical Society, 8 p.m. Ordinary.
TUESDAY, March 16th.—Pathological Society, 8 p.m. Ordinary.
ROYAL INSTITUTION, 3 p.m. Mr. A. H. Garrod, "On Animal Locomotion on Land, in the Air, and in Water."
STATISTICAL SOCIETY. Mr. Gro. H. Darwin: "Marriages between Cousins in England, and their Effects."
WEDNESDAY, March 17th.—Royal College of Physicians, 5 p.m. Dr. Beale, "On Life, and on Vital Action in Health and Disease."

VACANCIES.

Southport Infirmary. House Surgeon. Salary, £100, with board. Applications to the Secretary, endorsed "House Surgeon."
Leominster Union. Medical Officer. Salary, £90, with fees extra. Apply to the Clerk to the Guardians.

Bradford Infirmary. Physician. Diplomas, &c., to be sent to the Secretary, 66 Market Street, Bradford.
St. Thomas's Hospital. Assistant Obstetric Physician: Applications, with testimonials, to be sent to the Treasurer, at the Hospital.
Hospital for Sick Children, London. Physician, and an Assistant Physician. Honorary testimonials, &c., to the Secretary, at the Hospital.

Central London Ophthalmic Hospital. Assistant Surgeon. Honorary Testimonials, &c., to the Secretary.

Infirmary of the City of London Union. Assistant Medical Officer and Dispenser. Salary, £100, with board and lodging. Forms of application at the Office, 61 Bartholomew Close, E.C.

Bristol Lunatic Asylum. Assistant Medical Superintendent. Salary, £80, with board, furnished apartments, &c. Applications to the Chairman of Committee, Council House, Bristol.

Township of Manchester. Resident Assistant Medical Officer for the Poor. Salary, £130, with furnished apartments, &c. Applications to the Clerk to the Guardians, New Bridge Street, Manchester.

Devon and Exeter Hospital. House Surgeon-Apothecary. Salary, £150, with board and residence. Applications to the Secretary, at Exeter.

Stratton Union. Medical Officer for combined districts. Salary, £80, with fees extra. Testimonials to the Clerk to the Guardians, Stratton, Cornwall.

Dover Union. Medical Officer. Salary, £70, with fees extra. Applications to the Clerk to the Guardians.

Southport Infirmary. Resident House Surgeon. Salary, £100, with board and lodging. Apply to Mr. Robinson, at the Infirmary.

APPOINTMENTS.

DUKE, Mr. T., M.A., Assistant House Surgeon to the Cumberland Infirmary, Carlisle.

DUNLOP, W. M., M.B., C.M. Univ. Glasg., Medical Officer for Nos. 1 and 2 Districts of the Woodbridge Union, Suffolk, Admiralty Surgeon and Agent for Aldborough (Southern portion), and Medical Officer to the Boyton Society Club.

ELLIOTT, C. B., M.R.C.S.E., L.R.C.P. Ed., Resident Medical Officer to the Colonial Hospital, Champion Bay.

ELLIS, J. L., L.K.Q.C.P.I., L.M., Assistant Medical Officer to the North Wales Counties Lunatic Asylum, Denbigh.

FOOT, R. H., M.D., T.C.D., L.R.C.S.I., Assistant Medical Superintendent of the Fife and Kinross Lunatic Asylum, Cupar.

GREWCOCK, Mr. G., Medical Officer for the Hopsley District of the Grantham Union.

HAWARD, J. W., F.R.C.S.E., L.R.C.P.L., an Assistant Surgeon to St. George's Hospital.

HITCHINS, T. H., M.R.C.S.E., Medical Officer of Health for the Shipston-on-Stour Rural Sanitary District.

HUNTER, W. L., M.B., Resident Medical Officer to the Lewes Infirmary.

JOHNSON, J., M.D. Univ. Ed., a Physician to the Tunbridge Wells Dispensary and Infirmary.

KARREK, P. Q., M.R.C.S.F., L.S.A.L., Accoucheur to the Torquay Lying-in Charity.

KENNEDY, H., M.B. Univ. Dub., F.K.Q.C.P.I., a Physician to Simpson's Hospital, Dublin.

LANKESTER, Mr. E. R., Professor of Comparative Anatomy in University College, London.

LAW, W. T., M.D. Ed., M.R.C.S.E., L.S.A., House Physician to the Seamen's Hospital, Greenwich.

ROBERTS, C. H., L.R.C.P.L., M.R.C.S.E., Medical Officer for No. 4 District of the Alderbury Union.

SAMPSON, H. M., M.R.C.S.E., Assistant House Surgeon and Dispenser to the Kent and Canterbury Hospital.

SPENCER, L. W., L.R.C.P., M.R.C.S., Medical Officer of Health for the Rural Districts around Preston.

TANNER, R., M.D. St. And., M.R.C.S.E., Medical Officer for the Ledbury District and the Workhouse of the Ledbury Union, Herefordshire.

TAYLOR, A. H., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer, &c., for the Kilgarvan Dispensary District of the Kenmare Union, co. Kerry.

WEBB, Mr. W. H., Assistant House Surgeon to the Salop Infirmary, Shrewsbury.

WILLIAMS, F., M.R.C.S.E., Medical Officer for the Kidwelly District of Llanelly Union.

Deaths.

BARNES.—On the 25th Feb., Christopher Hewatson Barnes, L.R.C.P. Ed., of Coleherne Terrace, South Kensington, aged 73.

BROWN.—On the 25th Feb., at Morningside Place, Edinburgh R. J. Brown, M.D.

EDMONDSON.—On the 23rd Feb., Thomas Robert Edmondson, L.R.C.P. Ed., of Stokesley, Yorkshire, aged 57.

ORMSBOD.—Found dead in bed, on the 23rd Feb., William Geo. Ormsbod, M.R.C.S.E., of Portland Square, Bristol.

RICHARDS.—On the 20th Feb., Wm. Moseley Richards, M.R.C.S.E., of Stourbridge.

THORNHILL.—On the 25th Feb., at Nenagh, William Thornhill, M.B., F.R.C.S.I., of Upper Pembroke Street, Dublin.

THE LUMLEIAN LECTURES.

ON LIFE, AND ON VITAL ACTION IN HEALTH AND DISEASE. (a)

By LIONEL S. BEALE, M.B., F.R.S.,
Physician to King's College Hospital.

LECTURE I.

MR. PRESIDENT AND GENTLEMEN,—The nature of life is a question which has engaged the attention of the most thoughtful of every age, and was, perhaps, one of the first enigmas that philosophic man essayed to solve. For more than two thousand years, the greatest among poets, philosophers, naturalists, divines, mathematicians, and, in later days, chemists, anatomists, physicists, surgeons, and physicians, have thought and speculated and investigated in the hope of finding out what life was. But physicists, as well as those who are opposed to their conclusions, are still obliged to speak of the *mystery of life*, and we may feel quite sure that this large question will engage the attention of philosophers yet to be, and will supply a theme for many an essay, ere the problem will be finally solved.

Can there be one amongst us who, contemplating the marvellous phenomena of man's organism from the first dawn of life to birth, and through infancy and childhood to maturity, old age, and death, has not longed to know more about the exact nature of the changes he observes and the causes of them, than he can learn at this time? And surely he who has studied and pondered over the minute changes accompanying the development and growth of tissues, the phenomena occurring in the same structures in disease, and the not less marvellous fact of

their cessation at death, must have witnessed, with sorrow and disappointment, attempts upon the part of some of the most popular of our scientific teachers to revert to doctrines almost identical with those held in the time of Lucretius, to stop speculation, save in one direction only, and to force the public to believe that all these wonderful changes are mechanical—to assure us in short that these and the phenomena of all worlds—beginning, duration, and end, are to be summed up in that grotesque formula,—from fiery cloud to fiery cloud. It would be more to the point if physical authority, instead of decreeing such final solution of the great problem of being, would, with the help of physics, give a more complete answer to the question "What am I?" than has yet been obtained, and clearly show that the *why*, the *how*, and the *whither*, need no longer puzzle the understanding.

The general conclusions we may feel inclined to accept will be much affected by the particular views to which we may lean concerning the nature of the changes occurring in matter that is alive, and it will be found that vital theories cannot be fully discussed without touching upon the most profound of our thoughts. It is not, therefore, surprising, that by the advocacy of rival doctrines, feelings should be aroused which are not favourable to the steady prosecution of scientific investigation, or compatible with calm deliberation and the discovery of truth. The discussion of such questions cannot be carried on, even in England, without warm controversy; and, occasionally, scientific ardour seems to sanction tactics which one would suppose had emanated from the code of the political propagandist rather than from that of the searcher after scientific truth.

With a tenacity of purpose, worthy of a better cause, it has been affirmed again and again that physical and chemical processes constitute the life of the higher animals; and, at this time, there is a considerable party who believe and teach physical doctrines of life. Nevertheless, it can hardly be doubted that of those who speak thus confidently many are perfectly aware that there are certain phenomena which occur in everything living that cannot be explained by physics and chemistry. No explanation is offered of the particular phenomena in question,

Delivered at the Royal College of Physicians on Friday, March 12th.

but, in direct contravention of the principles upon which science rests, it is asserted that all phenomena are physical; some investigators apparently preferring to strengthen a party manifesting a certain definite tendency in thought than to aim at scientific accuracy and work on in a spirit of scientific independence.

Free speculation and the framing of hypotheses stimulates and encourages inquiry, and ought not to be opposed, but scientific speculation must be controlled by observation and experiment. Even purely conjectural propositions which arise from time to time in the mind, not unfrequently form the starting point of new lines of scientific inquiry. Nay, I believe that but for the mental pleasure derived from speculation and contemplation, it is doubtful whether original observers would be able to complete the tasks they set themselves to perform, tasks often lasting for months or years, and depending upon the steady prosecution of observation and experiment, in the course of which failure, disappointment, and the consciousness of lost time will be found to make a large item in the account. Scientific men must exercise their imagination, though at the same time they must control it. Observers probably differ from one another less as regards capacity for imagining than in the judgment they display in the publication of the results of imaginative inquiry. One man, perhaps, may examine carefully and then cast away hosts of ideas that another would gladly seize upon and bring under public notice at the earliest possible moment as thoughts that ought to move the world. Anyone having enthusiasm, who pursues a definite line of inquiry, will naturally desire to press on into the region just beyond the limits of observation and experiment; and this tendency is advantageous, for it often leads to new discovery. But of late scientific men, boasting of their exactness, have tried to drag us into very remote regions of conjecture, and insist that we shall accept, as literally true, all they discover in their imagination concerning the potentialities of imaginary atoms.

And not only so, but it has been more than suggested that some of the facts of the imagination upon which certain very old doctrines, recently revived, are based, cannot be made evident to people generally, but are only thoroughly understood by a very limited number of privileged persons. It is, therefore, a necessity that information so distributed should only be dispensable by a select few. But if we really study some of the hasty generalisations recently put forward, we shall find that after all they are little more than the opinions of one or two scientific speculators, having remarkable confidence in the infallible nature of their own opinions. Their unbounded faith has led many to accept their statements as literally true; and, by degrees, a powerful party has been formed. Now, no reasonable objection ought to be made to a combination among those who agree in their views of nature for the purpose of spreading the truths they have discovered, and endeavouring to gain for them the greatest publicity. The more widely and the more quickly facts are spread after they have been proved to be true the better for investigators and for students. But that a few scientific men who have committed themselves to a particular set of doctrines, or that any one scientific man should, upon matters of science, speak as it were *ex cathedra*, and declare a particular doctrine concerning the origin and formation of all things to be absolutely true, should praise in highly extravagant terms those who side with him, and stigmatise those who do not at once accept his views, or who differ from him in opinion as unworthy of credit, or as weak, or foolish, or savage, cannot be right or to the advantage of science. Such a course, if supported by many scientific men, and if sanctioned by public opinion, would surely be extremely prejudicial to liberty of thought and freedom of inquiry, for would it not soon lead to the establishment of a power that, instead of proposing, would decree; and, being convinced of its infallibility, would not hesitate to promulgate it? Nay, there is manifestly, at this time, a strong desire to establish a new power in connection with science and philosophy which would be contrary to the first principles of English thought and destructive of progress.

I venture to think that enthusiastic disciples of physical life science have recently seized far too much of the world of life and assumed that it was their own, and have claimed privileges which do not and ought not to belong to investigators and teachers—especially the privilege of enjoying with only a very few other highly gifted persons, a monopoly of the work of extracting scientific truth from the depths of the imagination. If some of the hypotheses now very popular can only be understood by a very small number of scientific men, is it impossible that the facts and arguments advanced against them should be made intelligible to a very large number of intelligent persons?

Many of this College, following the noble example set by the most illustrious of their predecessors, have done their utmost to extend the boundaries of medical science, and among our number are not a few who have taken an active part in the purely scientific work of the present century. The scientific as well as the practical aspect of medicine has ever been well represented in the College Lectures, but many circumstances seem to me to render it desirable, that those among us, who, favoured by circumstances, and having a natural bent for scientific pursuits, should do their utmost to maintain the high reputation for pure science won by their predecessors; and, as far as they have the power, hand down the honoured precepts to those who shall succeed. Such considerations, Sir, I hope may afford some justification for the course I shall take in directing attention to debated questions connected with life, which I fear may be deemed by some out of place here, in the Theatre of the Royal College of Physicians. But I may also plead, that one who has long been a teacher of physiology, and has had the honour of receiving a Baly Medal, may not unnaturally desire to ask this College and the profession to consider with him phenomena of the greatest interest, and which are most intimately connected with individual life in a state of health and disease. But above all, I have been affected by the circumstance that, at this time, we are overwhelmed and confused with the most conflicting statements as regards even the simplest facts of life. We have no solid foundation upon which to build the fundamental principles of our science, for are we not, many times in each year, enjoined to accept as true the doctrines of a purely conjectural philosophy, based upon conjectural discoveries concerning matter and atomic phenomena?

To the doctrines now generally taught and fast becoming very widely diffused, I am and have been strongly opposed. In certain particulars those doctrines are in conflict with views based upon well-observed facts, in relation to the growth and multiplication of every known form of living matter, and the formation of the tissues of living beings. Many observations, though repeated again and again, must be entirely erroneous if the positive statements recently made concerning the phenomena of living beings are true. It may be presumptuous perhaps to suggest that the conclusions arrived at by me many years ago ought not to have been wholly ignored by authorities, who have expressed themselves in very confident language concerning the physical nature of life, but people have been informed again and again that all the phenomena of living beings are due to physical changes, although it has been pointed out, that phenomena, characteristic of every kind of living matter, cannot be so explained. I have for many years pleaded in vain, that, for example, an attempt should be made to explain the movements of an amoeba, or a mucus corpuscle by physico-chemical action. But, instead of being answered, I am twitted with belonging to an institution famous for its orthodoxy. Old assertions are again repeated, and it is dogmatically declared in the plainest language that *all living things are machines and that all their actions are mechanical*.

It is, therefore, right as it seems to me, now to proceed a step further, and challenge the supporters of the physical theory of life, to publicly reply to the objections urged against the statements they have made. For has not the time arrived when the facts and arguments upon both sides might be summed up and judgment given, whether the physical doctrine of life is justified by the scientific know-

ledge of the time in which we live; or whether on the other hand it is not a thoroughly unscientific inference, based only upon the facts of the imagination, and opposed to facts of observation?

In the physical domain, as has been well said, consequence follows its antecedent with unerring certainty. What will happen under certain given circumstances can be stated with exactness and premised beforehand. But it is not so with the living world. It has yet to be proved that for every change there is a direct consequence of antecedent physical change. We cannot predicate of vital as we can of physical phenomena. We have not the certainty of physical law. Nevertheless, with amazing confidence, not, however, resulting from knowledge, some declare that the difference is to be easily accounted for by the greater complexity of the circumstances and conditions which obtain as regards vital phenomena. When, it is affirmed, by further investigation these circumstances shall have been fully investigated, man, we are assured, will be able to define, with absolute certainty and unerring precision, the particular living form which shall result from the development, under certain given conditions, of a particle of colourless transparent matter which represents the earliest stage of being of countless numbers of very different creatures. And yet changes, characteristic of every form of living matter, have been scarcely alluded to by the upholders of this notion. It must indeed have struck many as a remarkable fact that so little has lately been said concerning the relation of life to matter. The connection between mind and body, mind and brain, mind and matter, has been very fully discussed, but the question of the connection between life and body has received far less attention, although the determination of the last is the preliminary inquiry which would naturally be presented for solution before the nature and relations of mind were touched upon.

Surely we who have been studying life in many forms, and under varying conditions,—who have, from early age, been familiar with the tissues and structural changes occurring in man and animals, in health and disease, ought to carefully examine the current statements about the physics of life, and try to prevent the wider diffusion of mere mechanical views, at least until it shall have been proved that they rest upon some solid foundation. We have been assured, over and over again, that we must accept a particular doctrine or nothing; but surely the alternative is not a very terrible one, for is it not conceivable that some may prefer being stigmatised as believers in nothing to the privilege of accepting as literally true highly conjectural propositions?

Ought we not to urge those who have assumed the responsibility of teaching physical doctrines of life to publicly reveal the facts, and clearly state the arguments upon which they rely for the establishment of the doctrines they assert to be true—doctrines which seem to be based upon mere discoveries of the imagination, though they are, it is to be regretted, believed and taught in the most ancient of our seats of learning, where, strange to say, Socratic philosophy and caution are still inculcated?

Among the doctrines referred to are the following:—

- The sun forms living beings.
- The brain and all organs have been built by the sun.
- All the actions of all things living are mechanical.
- All things living are machines.
- Living organisms, as well as crystals, are the products of molecular forces.
- The mind, the intellect, the will, thoughts and emotions, as well as the body, were once latent in a fiery cloud.
- The present world and all its inhabitants, past and present, as well as those to come, lay potentially in the matter which was once cosmic dust.
- The lowest forms of living approximate very closely to non-living material.
- Life and material forces—only atoms and atomic forces—have been and are concerned in the formation of all things, living as well as non-living.

Up to this time no one has succeeded in showing that the above propositions contain the vestige of a substratum of truth, and it would have been easy to have added several others to the above list, of which the same remark would be correct. Those who force such views upon public attention incur a serious responsibility, but I am not sure if scientific men who strongly disapprove of the course taken, and who know full well that many of the extravagant assertions now made in the name of science, and from a scientific platform, cannot be supported by facts, do not, by their silence, incur a responsibility equally grave, inasmuch as they permit arguments which they know to be unsound, to be advanced in the name of science without objecting to them.

And now, Sir, I think I cannot better show how fully sensible I am of the high honour you have conferred upon me by appointing me to deliver these lectures to the College and the profession, than by asking of you permission to resign, whatever authority the position of Lunuleian lecturer may have given; for I would come before you as a student who, after studying and working for many years, desires in as plain a way and as briefly as he can, to speak of some of the things he has seen, and is anxious to indicate, as far as he is able to do so, the broad general principles which seem to be deducible from his observations.

Much of what I have to tell is simple, and will easily be understood, and there is nothing that I have found out that might not have been found out by another had the same means of inquiry been adopted, and had the work been patiently carried on for as long a time. Far from laying claim to the possession of any unusual powers or privileges of investigation, I shall be quite content if I am credited with the power of being able to see as correctly as my contemporaries.

The preparations upon which my inferences are based have been shown to others, and not a few were exhibited in this theatre soon after they had been made. It is upon demonstration that I rely, and if I am not convinced that opponents who have never seen my specimens know much more about them than I do, who have carefully studied them for hours under very high magnifying powers, on many different occasions, I hope I shall not be considered a very unreasonable and prejudiced person.

In the course of six lectures which I delivered to the College in the spring of 1861, and which were published soon afterwards, and in the course of the same year translated into German by my friend, Professor Victor Carus, of Leipzig, I directed attention to the remarkable characters of *living matter*, and pointed out how this could be distinguished throughout nature. (a).

I also showed that in nutrition the *tabulum* always gained access to the living matter, and that by and out of this latter alone tissue was formed, the very matter that was once living becoming converted into the tissue. Specimens of the living matter were exhibited, some of which were taken from the lowest organisms, and others from the tissues of the higher vegetables and animals, and from man. The varying proportion of living matter in corresponding tissues at different ages was also demonstrated in cuticle, cartilage, muscle, nerve, and other tissues. The living matter was called *germinal matter*, which term has been since replaced by the short and more convenient word *bioplasm*; and the matter formed from it was termed *formed material*, because it was shown that all tissue, "intercellular substance," and matters resulting from changes in the so-called cell were formed from the *bioplasm* only.

It was also shown that masses of *bioplasm*, after reaching a

(a) As much misconception has arisen as to the exact date of my observations on account of frequent references on the part of authorities to observations of Max. Schultze and Kuhne, while mine were wholly ignored, it is only right to draw attention to the fact that Max. Schultze's "Das Protoplasma" was published in 1863, nearly two years after my lectures appeared, while Kuhne's "Untersuchungen über das Protoplasma" did not appear till in 1864.

certain size, usually less than the 1-1000th of an inch in diameter underwent division, and that as soon as any mass of bioplasm attained a certain definite size (which differs in different creatures and textures, but which is constant for the same), it divided, or portions moved away; and, at length, detached themselves from it. If the bioplasm were to continue to grow, the distance to be traversed by the nutrient matter, before the inmost parts were reached, would soon become so great that these would be practically beyond reach, and could not be nourished or subjected to the constant action of currents of fluid. Death would begin in the central part of such a mass, and would soon involve particle after particle as its ravages extended outwards, until the whole of the living mass was dead. There are many circumstances connected with the life of a mass of bioplasm which render its growth without division and subdivision a most improbable event. With the exception of that fanciful sheet of living matter once supposed to grow in the sea at very great depths—never seen, but received in undoubting faith by the critical Strauss—that so-called Bathybius which was evolved from the depths of the imagination at a time when a primeval physical basis of all life was particularly wanted by certain advocates of evolution—with this exception, I repeat, large masses of living matter exist not.

In man and the higher animals, it is the exception to find a single mass of bioplasm, which measures as much as the one-thousandth of an inch in any direction. It is not wonderful that particles of matter so small, especially as they are also colourless and structureless, should have been, for a long time, passed over as of little importance, and almost ignored by some anatomists. In many drawings of tissues which contain numerous masses of bioplasm, not one is represented, for it was supposed that the tissue was formed independently of such particles. But the evidence in favour of the view that it is from these small masses of living matter that all tissue grows is incontrovertible. Without them nothing characteristic of a living organism is formed. These, and not the formed tissues, are the seat of nutrition, formation, and differentiation, and in them is the sole source of metabolic power.

It was not to be expected that conclusions differing so widely from those entertained at the time by most observers, and so opposed to the general inferences concerning the nature of vital phenomena, would be accepted without the most thorough criticism. For that every conscientious worker ought to hope. I have been at all times ready to demonstrate the facts upon which my conclusions are based; and have been prepared to modify my views or abandon them if errors should be discovered, and mistakes plainly pointed out. Every student of nature must be ready to have his conclusions at least considerably modified by those who follow him, and who go over the same ground with advantages, necessarily greater than those which he, as a labourer in what was then a new field, could enjoy.

Nor can an observer, living in times when materialism happens to be in the ascendant, at least among scientific men, and who is so unfortunate in his observations as to light upon facts which seem to him to support a view of the nature of life not in accordance with the tendency of the thought of his day, expect that his researches will be very kindly received or considerately treated. All this must be accepted; but is it not very doubtful whether the energy displayed during the last few years in pressing ill-founded and extravagant generalisations upon public attention, will be of advantage, either by exciting an increased desire for scientific information, or by raising science in the esteem of well-educated persons?

It is, indeed, difficult for an observer to decide upon the course he ought to take in these days to bring his observations under the notice of other persons interested in similar inquiries. No doubt a certain humility of demeanour towards some who, I venture to think, assume that they occupy a position not sanctioned by custom, nor to be defended as an innovation likely to promote the interests of science, might obtain for an observer the

privilege of working without serious opposition, and perhaps without hostile notice. But I venture to think that although a scientific man ought not to take any active steps to force his views before his contemporaries, or to gain for them the greatest possible notoriety, he may fairly expect that his results should be considered and weighed under the same advantages as those enjoyed by other members of the scientific body. Of course he should be careful not to excite opposition, but it would be unreasonable to expect him to be always making efforts to conciliate possible and probable opponents, or to passively submit to be roughly silenced by a clique, because his views and opinions are opposed to unproved and unprovable dicta, promulgated by them.

In theory, at least as it seems to me, every worker appeals to, and ought to be protected by, scientific public opinion, which perhaps, hardly as yet existing in England, is slowly, but it is to be hoped surely, developing itself. An observer should endeavour to accurately describe what he has seen; and, having published the results of his inquiries, should announce, in the only way open to him, that such a work has been completed, and can be obtained by those who desire to see it. It will however, save under very exceptional circumstances, hardly be possible for him to get attention directed to his observations without some sacrifice of independence to which no real worker will like to submit, although the only alternative may be to be ignored or condemned as one not fitted to survive in the struggle for intellectual existence.

THE CANTOR LECTURES AT THE SOCIETY OF ARTS FOR 1875.

ON ALCOHOL.

By B. W. RICHARDSON, M.D., F.R.S.

(Continued from page 202.)

Alcoholic phthisis, or the consumption of drunkards.—There are yet other and more prolonged, and more certainly fatal mischiefs induced in the lungs by the persistent resort to alcohol; and to one of these I would direct special attention. It is that deterioration of lung-tissue to which, in the year 1864, I gave originally the name of *alcoholic phthisis or the consumption of drunkards*. The facts came before me at first in this manner. In a public hospital to which I acted as physician, I had brought before me, in the course of many years, two thousand persons who were suffering from consumption. I gathered the history of the lives of these, and of the reasons why they had passed into the all but hopeless malady from which they suffered. In my analysis of these histories I found that the causes of the malady altogether were, in the great majority of instances, predisposition from hereditary taint, exposure to impure air, want, or certain other allied causes. But the analysis being conducted rigidly, I discovered that when every individual instance had been classified as due to the causes stated above, there remained thirty-six persons, or nearly two per cent. who were excluded from them, who appeared to suffer purely from the effects of alcohol, and in whom the consumption had been brought into existence by the use of alcohol.

The added observations of eleven years since the above-named fact was recorded in the *Social Science Review*, as a new fact in the history of the disease, only served to prove in the minds of other men as well as my own the truth of the record.

The persons who succumb to this deterioration of structure induced by alcohol, are not the exceedingly young, neither are they the old. They are usually over twenty-eight and under fifty-five. The average age may be taken as forty-eight. They are persons of whom it is never ex-

pected that their death will be from consumption; they are generally males. They are probably considered very healthy: men who can endure anything—sit up late at night, run the extreme of amusements, and yet get through a large amount of business. They sleep well, eat pretty well, and drink very well. They are often men of excellent build of body, and of active minds and habits. They are not a class of drinkers of strong drinks, who sleep long, take little exercise, and grow heavy, waxy, pale—

“Sleek-headed men, and such as sleep o' nights.”

On the contrary, they take moderate rest, and see as much as they can. Neither in the ordinary sense are they drunkards; they may never have been intoxicated in the whole course of their lives, but they partake freely of any and every alcoholic drink that comes in their way, and they bear alcohol with a tolerance that is remarkable to observers. They are hard drinkers as distinguished from sots. Beer is to them as water, wine is weak; the only thing that upsets them is stiff grog in relays, or a mixture of spirituous drinks carried to the extent of what they call, in grim joke—in which death surely joins—“piling the agony.”

As a rule these cannot live in what they consider to be comfort without a daily excess of alcohol, which excess must needs be renewed on emergencies, if there be greater amount of work to be done, less sleep to be secured, or more life to be lived.

As specimens of animal build these persons are often models of organic symmetry and power. In fact, they resist the enemy they court for so long a time because of the perfection of their organisation. More than half of those whom I have seen stricken down with alcoholic phthisis have expressed that they had never had a day's illness in their lives before; but questioned closely it was found that none of them had actually been quite well. Some of them had suffered from gout, others from rheumatism or neuralgia. They had felt severely any depression, such as that which arises from a cold; and if they had been subjected suddenly to causes of excitement or exhaustion, they detected, without actually realising its full meaning, that their balance of power against weakness was reduced, that the end of the beam called strength was rising, and that an extra quantity of alcohol was required to bring back equilibrium. As a rule men of this class are thoughtless of their own health and their own prospects, for they have an abundant original store of energy. They are designated as “happy-go-lucky” men, or as men who “always fall on their feet,” which truly they do, but not without injury.

The countenance of the alcoholic consumptive differs from that which is usually considered the countenance of the consumptive person, and equally from that which all the world adjudges as belonging to the man who indulges freely in strong drink. Who does not remember the wan, pale, sunken cheek of the youth on whom ordinary consumption has set its mark? And who, again, does not recall the *facies alcoholica*—the blotched skin, the purple red nose, the dull, protruding eye, the vacant state of the confirmed sot? The alcoholic consumptive has none of these characteristics. His face is the best part of him in all his history. When his muscles have lost their power and his clothes hang loosely on his shrunken limbs, he is still of fair proportion in the face; he has little pallor and he is expressive in feature, so that his friends are apt to be deceived and to believe that there must be hope for his recovery, even when he is beyond every hope. I remember being actually taken aback on one occasion on finding, in a man who seemed, from his face, to be in perfect health, how completely destroyed his lungs were by the encroachments of disease; and I cannot be surprised, therefore, that others, less informed, should share in such an imperception of danger when it is close at hand. Nobody, in a word, “pities the looks” of these sufferers, and good eyes are necessary to learn that pity as called for.

The phenomena are not always developed at a time when the sufferer from them is indulging most freely in alcohol. On the contrary, it is by no means uncommon that the habit of excessive indulgence has been stopped for some time previously to their development. The reasons assigned by the patients for abstinence vary. One man may have been strongly advised by his friends to desist, or may himself have undergone a certain measure of reform; another has been led by the reading or hearing of arguments on temperance; a third, by want of means to obtain the indulgence; but by far the larger number tell you that a time came when the desire for so much drink did not occur to them. They will state that they tried the round of the various spirits, but found that none agreed with them as before, so that at last they were driven to rely on beer as the only drink they cared for. We read all this off clearly enough from a physiological point of view. We see that, in fact, the body has been resisting the alcohol; that it could not do away with it as it did when all the excreting organs were in their full prime; and that those drinks only can be borne in which the amount of alcohol is least, but the sufferer does not comprehend the fact, and therefore he not unfrequently concludes that his increasing languor and debility are due to the necessary withdrawal of the stimulus on which he seems to have been actually feeding during the greater part of his life.

The signs which first indicate failure of health are usually those of acute pleurisy. There is pain in the side, quick, sharp, startling. The term “stitch” in the side is commonly applied to this pain, and is expressive enough. After a time the pain becomes continuous, and when it subsides, suppressed breathing, or difficulty of filling the chest, is at once felt and recognised. This difficulty is due to the circumstance that a portion of lung has become adherent to the inner surface of the chest. The next sign indicating that the disease (consumption) is present, is, usually, vomiting of blood. In two-thirds of the examples to which my attention has been directed this has been the sign that has first caused serious alarm. It is commonly on this event that the physician is called in, who examines the chest with the stethoscope, and finds too often a condition that is hopeless. From the appearance of that sign all is down, down, down towards the grave.

There is no form of consumption so fatal as that from alcohol. Medicines affect the disease but little, the most judicious diet fails, and change of air accomplishes but slight real good. The sick man with this consumption may linger longer on the highway to dissolution than does his younger companion, but there is this difference between them, that the younger companion does often leave the highway to find a by-path to health, while the other never leaves it, but struggles on straight to the end. In plain terms, there is no remedy whatever for alcoholic phthisis. It may be delayed in its course, but it is never cured, and not unfrequently instead of being delayed it runs on to a fatal termination more rapidly than is common to any other type of the disorder.

The origin of this series of changes from alcohol is, as you will perceive, again in the membranes. The course of it is through the membranous tissues. The vessels give way after a severe congestive condition, and blood is exuded, or extravasated into the lung. There are here two diagrams in water tint, in which both these conditions are faithfully depicted, and to these is added a third, which shows in some, but in an imperfect manner, the course of the after destruction of the substances of the pulmonary organs.

(To be continued.)

A MEETING of the Fellows of the Royal College of Surgeons in Ireland will be held on Thursday, the 18th of March, at half-past two o'clock, to witness the election of a Professor of Chemistry, including practical chemistry, in room of Dr. Reynolds, resigned.

ON THE RELATIONS BETWEEN THE CLINICAL HISTORY AND HISTOLOGY OF TUMOURS (a).

By ROBERT McDONNELL, M.D., F.R.S.,
Surgeon to Dr. Steevens' Hospital.

BEFORE offering some observations on the relations existing between the clinical history and histology of tumours, I wish to lay before the Society some cases which I shall use in illustration of the observations which I have to make in conclusion. These cases which I am about to bring under the notice of the Society, all illustrate tumours belonging to the group of the connective tissue series, varying, however, much as well in their microscopic characters as in their clinical history, and also very different in their degree of malignancy or tendency to return after removal.

CASE I.—Mary Reilly, 20 years of age, a health-looking country girl, was admitted into Steevens' Hospital on 23rd July, 1869. The day after admission a tumour, weighing two pounds, was removed from the right gluteal region. It had been of slow growth, extending over more than six years; it was globular, hard, and painless. She left hospital on 3rd September, subsequently went to America, but returned from there, and I have lately had an opportunity of seeing her. There has been no return of the complaint. This tumour on being examined microscopically was found to be composed of dense fibrous tissue. It was, in fact, a good example of the simplest form of fibrous tumour, yielded gelatine on boiling, and was of uniform structure throughout. Sections of this tumour are placed on the table under the microscopes.

CASE II.—John Farrell, when 45 years of age, was operated on by Mr. Colles for a large tumour which had been growing in the axilla for seven years. Three years later (26th February, 1867) he was again admitted to Steevens' Hospital, the tumour having returned. It had this time presented the appearances seen in the accompanying drawing, and was a second time removed by operation. On the 26th June, 1869, he was a third time operated on, the tumour having recurred in the same place. The structure of this tumour was remarkable. It was composed of a large number of encapsuled fatty masses varying in size from that of a walnut to that of a small hen's egg. Some of these fell from their capsules on the floor at the time of the operation. Microscopic examinations showed them to be fatty tumours, although to the naked eye the smaller ones seemed gelatinous in structure. The fat cells were found to be entangled in a network of areolar tissue. The patient recovered from the third operation, but I have not heard of him recently.

CASE III.—Mary M——, aged 30 years, was admitted to Steevens' Hospital on 4th March, 1874, suffering from a large and hideous tumour of the orbit. I removed it on the 14th of March. The appearances are seen in the accompanying photograph. The disease commenced when she was 15 or 16 years of age. So long as twelve years ago it had been removed for the first time by Dr. Leeper, of Loughall. The patient left hospital on the 19th of April, after the second operation. I have since heard from Dr. Leeper that, as yet, there is no sign of a return of the tumour. This case, which has been published in full in the *Irish Hospital Gazette*, July 1st, 1874, proved on microscopic examination to be composed of minute spindle cells and small round cells, such as are found in

sarcomatous tumours, but much smaller. Portions of this tumour are also exhibited in the microscopes on the table. This tumour has no doubt grown by proliferation of the cells of the neuroglia of Virchow, probably at first in the retina, subsequently in the optic nerve. If it returns it is probable that it may return in the neuroglia within the cranium.

CASE IV.—Thomas Power, 12 years of age, was admitted to Steevens' Hospital on the 24th July, 1874, suffering from tumour of the lower jaw of eighteen months' growth. It had commenced to grow at the root of the canine tooth of the lower jaw, upon the left side. It increased much more rapidly during the last three or four months, until it attained the size seen in this preparation, and presented the appearance seen in the accompanying photograph. It was free from pain, and presented a firm, uniform, hard, and at some parts elastic feeling to the touch. The teeth were loosely embedded in the tumour. There was no glandular enlargement, but the parotid glands felt slightly indurated. It was removed on 8th August, 1874, the bone being sawn through on each side as far back as the angles of the jaw. The patient made a good recovery, and left hospital on 25th August, 1874. This tumour was found to be a typical example of the sarcoma, known as "giant-cell sarcoma," which name has been given to it by Virchow. It is a variety of sarcoma containing very large cells filled with smaller ones—brood cells, as they are not badly named. These large cells are sometimes round, sometimes polymorphous, and supplied with many processes or offshoots. They are found to occur normally in the medulla of the bones of the fetus, hence sometimes called myeloid cells. True myeloid cells, however, are not so large as the brood cells found in tumours. They are the largest unformed protoplasmic collections that have been met with in man. They sometimes contain from half-a-dozen to even thirty or more lesser cells without nuclei. Their origin, by a series of transformations from simple cells, is generally easily traced out. They sometimes occur sporadically in various forms of sarcoma, fibro-sarcoma granulation and myxo-sarcomata. They are frequent in central, less so in periosteal sarcomata of the bones. Billroth has seen them in muscle sarcoma. Similar protoplasmic masses have been described by Klein in his work on the Lymphatic System. He says: "I have come across several times in the normal as well as in the chronically inflamed omentum endothelial cells which presented the characters of giant cells—myeloplaxes—that

(a) Read before the Surgical Society of Ireland, Feb. 12. The discussion will be found at page 229.

is, protoplasmic masses containing five to ten nuclei." Sections of this tumour are also exhibited in the microscopes on the table.

CASE V.—Michael Leonard, aged 60 years, was admitted to Steevens' Hospital 23rd June, 1873. The accompanying photograph shows the situation and dimensions of the morbid growth from which this patient suffered. The tumour was free from pain, and in fact caused him no suffering or trouble, save from its weight and bulk. I removed it on 28th June. The patient recovered and left hospital on 4th August. The microscopic structure of this tumour proved it to be an example of the spindle-cell sarcoma, not uncommon in the testis. Portions of this tumour may be seen in the microscopes on the table. As is usual in such cases, this disease has returned. I have heard from Dr. J. P. Nolan, who sent the case to me, that the disease has reappeared at Poupard's ligament, and extends into the abdomen. It is to the microscopic structure of the tumour which I wish to direct attention. I would merely add, that from what we know of the clinical history and ultimate progress of these cases, it is probable that the disease has returned, not in the lymphatic glands, but in the connective tissue of the cord and abdominal viscera.

CASE VI.—Mrs. S—, when 64 years of age, suffered from a large tumour of the breast, the appearance and dimensions of which are seen in the accompanying drawing. It was, when this drawing was taken, a two years' growth, free from pain, causing no uneasiness, except from its weight and bulk. I removed it for the first time on 25th October, 1868. It weighed within a couple of ounces of ten pounds. On 23rd November, 1869, a return growth in the same situation was removed by me, weighing two pounds. The disease recurred as a local affection, ulcerated, and carried off the patient in the early part of the year 1871. The structure of this tumour, which may be seen under the microscopes on the table, showed that it also was a spindle-cell sarcoma, but the entire tumour was found to be rich in mucine. A small part of the tumour, when bruised in a mortar with silver sand and shaken with water, yielded an abundance of viscid fluid thicker than flax-seed tea, limpid, alkaline, free from albumen, and containing mucins in large quantity. This was precipitated by acetic acid, and was insoluble in excess of that reagent. Liquor potassæ removed the viscosity, especially when boiled with the fluid. This tumour may be regarded as an example of myxo-sarcoma, resembling in its structure and general composition mucous tissue, with this difference only, that in the mucous tissue the cells are generally more stellate, and the spindle cells fewer in number; in this tumour spindle cells and round cells predominate.

CASE VII.—James J—, 21 years of age, was admitted to Steevens' Hospital on 19th December, 1874, under the care of my colleague, Mr. Colles. Eight months before he had received an injury of the right leg, in consequence of which he was unable to work for some time. A tumour appeared on the inner surface of the shaft of the tibia below the knee-joint. He was admitted to Steevens' Hospital on 23rd May, 1874. The tumour increased in size. Amputation was recommended, but the patient left hospital, not being willing to undergo the operation. He returned, however, in December, the tumour having increased to an enormous size. Mr. Colles amputated the limb on 22nd December. The microscopic structure of this tumour, some specimens of which may be seen in the microscopes, taken from the upper part of the morbid mass, which lie on the table, shows the small round cells with which the histologist is familiar, indicating round-cell sarcoma, a form of intense malignancy. The disease has eaten through the tibia, attacked all the surrounding structures, and assailed the knee-joint. The cellular elements of the growth vastly predominate. It may be regarded as being almost entirely composed of rapidly proliferating cells, which do not go beyond the stage of round cells. It is one of those morbid growths in which the energy of the

disease expends itself in reproduction, and in which there is no tendency to develop into any form of mature tissue.

I have selected these cases to illustrate my observations, because they all belong to one class of growths. They show the various degrees of malignancy which are to be met with within the category of the connective tissue series of morbid growths. The first case had no tendency to return; the second, although of simple fatty structure, was recurrent; while the later cases are of more intense malignancy. Yet none of them could be regarded by the skilled microscopist as carcinomata.

Mr. Savory, in an admirable lecture which he lately delivered on the Structure of Tumours in Relation to their Character and Clinical History, observes "that it must be confessed that it is no light task for a student to grapple with our present knowledge of the subject of tumours." I would add that this undoubted difficulty arising from the natural obscurity of a subject admittedly hard of elucidation is much increased by the fact that many clinical teachers entertain erroneous ideas as to the true relationship between histological and clinical observations as regards tumours. So far as classification of morbid growths is concerned the progress made of late years has been immense. The study of the development of the tissues of the embryo, the recent advances in physiology regarding our knowledge of growth of tissues, wandering cells, and not only the development of granulation, but the "first starts for special development" which peculiar tissues implant on granulation (as in skin grafting, for instance), these and other circumstances have tended profoundly to modify our views with regard to the genesis of tumours. With these new views, a new basis of classification has sprung up, and a new nomenclature has been adopted. In fact, a new language is spoken, which is an unknown tongue to those who have not taken some pains to keep *au courant* with the advances of physiology and histology. Such terms as sarcoma, heterologous, homologous, &c., have significations different from what they used to have. Even the words cancer and malignant, applied to tumours, are rather popular expressions than terms with a definite precise meaning. The unfortunate student, as he attends to his clinical studies, is bewildered by a jargon of words meaning one thing in the mouth of one teacher and another from the lips of a second. The clinical classification of tumours and the classification derived from structure cannot coincide. At present there is a jarring between the two. It becomes every day more certain that for purposes of classification we must look to structure. The practitioner asks, "Is this tumour malignant?" The histologist replies, "I cannot tell you that, for you cannot yourself define for me what you mean by the term malignant;" "but," he continues, "I can tell what the structure of the tumour is so as to classify it with others, and so, having, as I may say, indicated the species, genus, and natural family to which it belongs, a key is given whereby the recorded experience of other observers may be turned to account when tumours identical in structure are met with."

Without some sound and comprehensive basis of classification it was as impossible for what may be called the science of tumours to make any real progress as it would be for botany or zoology to progress without classification. Various observers in different parts of the world cannot co-operate with each other in any science unless some common scheme of classification enables them to know what they are talking about. For progress in the investigation of the science of tumours classification was essential. Virchow may be said to have done for the classification of tumours what Linnæus did for botany.

The General Anatomy of Bichat, the Embryology of Haller and Hunter, had as yet thrown little light on histogenesis. It was not until the school of Dollinger paved the way for the history of development, and Schwann and J. Müller had made the finest elements of the tissues the objects of scientific research that Virchow was enabled little by little to construct a classification of tumours based upon their anatomy and mode of development. Of late years the

difference in structure of tumours has attained even a greater importance than Virchow assigned to it. He sought to prove that all new growths originate from the cellular elements of the connective tissue—a view modified by what is daily being added to our knowledge of the so-called mobile connective tissue corpuscles and the various forms of protoplasm recognised in colourless blood corpuscles, wandering cells, pus corpuscles, endothelium, &c.

A further modification of Virchow's doctrine, or perhaps one should say an extension of it, in a definite direction, arose from Thiersch's supposition of the necessity of a genetic origin of tumours. This beautiful theory of Thiersch is, in fact, an extension to morbid growths of that already propounded in physiology by Remak. It supposes that each of the three layers of the germinal membrane of the embryo can only produce tissues of a like kind throughout the life of the individual. In accordance with this theory tumours of the connective tissue series (sarcomata) are separated by a distinct theoretic line from carcinomata and all epithelial structures.

Waldeyer and the eminent scientific surgeon and pathologist, Billroth, have adopted the hypothesis of Thiersch. The latter says: "The more I feel obliged to suppose that in the perfect organism there are no entirely indifferent cells, but that the elements of the middle germ-layer of the embryo and of the two epithelial layers are always somewhat in opposition, the more I am inclined to use this fundamental histogenetic fact for the development and division of tumours." In accordance with this he only calls those tumours true carcinomata which have a formation similar to that of true epithelial glands (not lymphatic glands), and whose cells are mostly true derivatives from true epithelium.

In the neighbourhood of epitheliomata and carcinomatous tumours, notably in young returning epitheliomata and surrounding those treated by caustics, there are usually numerous young, small round cells infiltrating the connective tissue portion of the tumour. The presence of epithelial elements probably gives a direction or a first start to further development, just as transplanted periosteum or skin epithelium gives a direction or first start towards a special cell development. Although one cannot help admiring the captivating theory of Thiersch, and even admitting its truth as very probable, yet I cannot agree with Billroth in thinking that the development from the germ-layers of the embryo can be regarded as a fundamental histogenetic fact for the development and division of tumours. The tissues springing from these germinal layers are too intricately blended together; so intricate, in fact, is their intermixture that it would be impossible to determine that any given tumour sprung exclusively from the tissue formation of any one layer.

Clinical surgeons and physicians find fault with the microscope because it fails to tell them what morbid growths are malignant or non-malignant. They expect the histologist to define what they cannot define themselves—malignancy. There is no boundary line dividing the territory of malignant tumours from that of benign tumours, as a river divides one country or province from another. We may seek in vain for any histologist who has made such an assertion. The histologist merely asserts that the classification of tumours made by clinical observers is unsatisfactory. The attempt to classify morbid growths as benign and malignant is as imperfect as though botanists attempted only to classify plants as poisonous and non-poisonous, edible and non-edible. For purposes of classification the microscope is invaluable in this direction; it has done much to advance the science of pathology. I am far from saying that there are not many tumours which it may perplex the most skilled histologist to assign to its proper class; but I have selected those cases which I have brought under the notice of the Society this evening on account of the comparative simplicity of their microscopic structure. To such tumours their proper place in the series of connective tissue tumours can be assigned. Each one of them can be compared with similar growths in other subjects and in other

lands. Thus, as time goes on, and as accurate observations are accumulated, we may hope to gain more certain knowledge of the clinical history, progress, and ultimate termination of cases which, without the aid of the microscope, would remain huddled together in one chaotic heap. Classification introduces order instead of confusion, it gives accurate and intelligible nomenclature instead of what is vague and obscure; it enables observers to co-operate with each other; it is a prime step in the progress of all science of observation.

As regards tumours, there is no other system of classification comparable (in the present day) with that based on their histogenetic characteristics as worked out by the microscope.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

C. J. B. WILLIAMS, M.D., F.R.S., President, in the Chair.

DEBATE ON DR. MARCET'S PAPER.

THE PRESIDENT had seen many cases of laryngeal phthisis, and agreed with Dr. Marcet, that it was rather a modification of ordinary phthisis than a disease in itself. The complication was a serious aggravation of phthisis, and hastened the fatal termination by adding distressing symptoms and interfering with the treatment. The cough was very harassing; it might be called a fruitless cough, as it was attended with little expectation. The loss of voice had a depressing effect on the patient. There was also, perhaps more frequently than Dr. Marcet seemed to think, difficult or rather painful deglutition, often from ulceration of the larynx rather than of the epiglottis. When the epiglottis was diseased, the passage of food over the glottis produced grievous irritation; hence it was necessary in such cases to give food in as bland a form as possible, so that a sufficient quantity might be taken; for the course of the disease was accelerated by any interference with nutrition. The general tendency of laryngeal phthisis was to hasten death; but he had known some exceptions in which, after indications of pulmonary disease were present, the larynx was attacked, and became apparently the chief seat of disease. He referred especially to one case of the kind where, although there were at first distinct symptoms of pulmonary disease, nothing was found in the lungs after death but a few patches of withered tubercle, while the larynx not only presented extensive tubercular disease, but there was necrosis of the cartilages; but such cases were exceptional. Constitutional remedies were very important; cod-liver oil, &c. He had been much disappointed in treating laryngeal phthisis, and, indeed, chronic laryngitis, by local remedies. In most cases nitrate of silver and similar articles did more harm than good. In a few cases, the application of nitrate of silver by Dr. Horace Green's method had been useful; but he had met with so many failures from this treatment, that he had laid it aside. The use of spray was more applicable, and sometimes more successful; but even with this the results had fallen short of his expectations. He concluded that it was only in a limited number of cases that these remedies were useful. Spray should be used in summer and hot inhalations in winter; he had found the use of spray in cold weather injurious. A weak solution of carbolic acid in the form of spray was useful; it acted as a soothing agent, and as an alterative of the secretion. He agreed with Dr. Marcet as to the offensive and acrid nature of the exhalation from the larynx in the disease; and for the correction of this, creasote, carbolic acid, and the oil of the *Pinus sylvestris*, were useful. Sometimes a very weak solution of nitrate of silver, of sulphate of copper, or of acetate of lead, allayed the irritation for a time. Inhalation was useful in cold weather; but it must be remembered that it was liable to produce perspiration, and hence the patient should be cautioned not to use it except at bedtime and when he was not exposed to cold. The various forms of inhaling apparatus showed much ingenuity, but the tubes were generally too small; they ought to be twice or three times as large. A simple and useful form which he employed was a jug of hot water containing the medicinal substance to be inhaled, the

patient inhaling under a napkin lying over his face and covering the jug. The medical substance to be inhaled must be volatile; it was sometimes recommended to add non-volatile metallic salts to the water; even iodine was volatilised with some difficulty. In general, creasote or carbolic acid, with hemlock, or in some cases chloroform, were most useful. The recommendation to use iodine both internally and externally deserved consideration. Many remedies might be given in oil or glycerine which were too irritating to be administered in other ways. Even water-vapour itself, in the form of spray, was irritating to the larynx, and of course more so when containing other substances; hence the addition of oil and glycerine was worthy of consideration.

Dr. DRYSDALE said that it seemed to him, from observation of many cases, that the prognosis in laryngeal phthisis was fatal, except where the patient could go to a warmer climate; and, under these circumstances, he had known a few cases where life had been prolonged for years, just as in other cases of phthisis. As a general rule, he thought that the course of laryngeal phthisis towards death was very rapid. He had seen relief produced by the inhalation of iodine vapour. As to the diagnosis, there was a difficulty, as had been well pointed out by Dr. Marcet, in distinguishing between laryngeal phthisis and syphilitic disease of the larynx; especially in such cases as one to which he referred, in which laryngeal phthisis occurred in a patient who presented distinct signs of syphilis.

Dr. THIN had visited Salt Lake City, and obtained some information from a medical man there. The plateau on which the city stood was about four thousand feet above the level of the sea. Among the native white population, he was informed, phthisis never occurred. Among the converts to Mormonism who came from the eastern parts of America and from Europe, there were sometimes persons, especially women, who had slight symptoms of phthisis before setting out; during the journey, the disease often became much aggravated; but after their arrival, unless they were in the very last stage of the malady, arrest and cure of the disease almost invariably took place. He believed that this fact was not generally known. He doubted the propriety of making scarifications of the larynx in laryngeal phthisis, as he believed that the resulting effusion might become a source of tuberculous growth.

THE SURGICAL SOCIETY OF IRELAND.

The Society met on Friday evening, the 12th February, the Vice-President, Dr. E. HAMILTON, in the chair.

Dr. McDONNELL read a paper

ON THE RELATIONS BETWEEN THE CLINICAL HISTORY AND HISTOLOGY OF TUMOURS,

which will be found at page 226.

The VICE-PRESIDENT said he should be glad to hear the remarks of any member of the Society on Dr. McDonnell's valuable paper. It was a matter of great importance to obtain anything like distinct ideas upon so obscure a subject.

Dr. CORLEY said this was a question of such importance that on the strength of having but one single specimen to bring before the Society, he ventured to read the short paper referred to. He could only regret that Dr. McDonnell's paper had not been before the Society previous to his bringing forward the case, because Dr. McDonnell had given *in extenso*, the views of which he (Dr. Corley) was only able to give a brief description. He was forcibly struck with Dr. McDonnell's observation that Thiersch's theory had a great deal to recommend itself in its simplicity and beauty as a means of classification for the use of students, seeing that it was impossible to separate tumours distinctly into those as growing from one particular layer of the germinal membrane. The case he had brought forward was a tumour which was unconnected either with the glandular or cutaneous surfaces. It was a connective tissue tumour, and still, on examination by the first pathologists of this city, it proved to be an epithelioma. It might, of course, be open to the argument that it could not grow close to the epithelium or the parotid gland without having embodied in it some of those structures. The clinical history of the case showed that it had no connection with the epithelial structure,

for it did not ulcerate through the skin, nor did it affect the parotid gland. He hoped that as cases of this kind turned up in future members would bring them forward to show how far this beautiful theory of Thiersch's could be supported or contravened, for next to the importance of establishing the truth of a theory was the proof of its untruth. They should feel much obliged to Dr. McDonnell for the trouble he had taken in bringing the subject before the Society.

Dr. PURSER thought that the great diversity of structure which is often found in different parts of the same tumour makes it very difficult to determine in a given case from which embryotic layer the tumour has sprung. The malignancy of tumours is entirely a question of degree. Malignant and non-malignant growths are not separated by any sharp line, but shade off gradually into each other; so that two tumours with pretty much the same anatomical structure will pursue—one an innocent, the other a malignant course. Nevertheless, the anatomical classification is the only one possible. From the mere structure of a tumour, whether healthy or morbid, could never be deduced its properties while living. A useful knowledge of tumours can only be gained by the common work of both clinical surgeons and histologists, the one observing the life-history of the growth, the other its anatomical structure.

Dr. McDONNELL said, if his paper had done nothing more than call forth what they had just heard from Dr. Purser he should be amply repaid for his trouble. The case Dr. Corley referred to he had not, unfortunately, had an opportunity of seeing, but it was not one of those cases he laid much stress upon, for this reason: it was most obscure and most difficult to determine the nature of it. Two of the most eminent, if not the most eminent microscopists in the city, their secretary Dr. Richardson and Dr. Purser, rather differed in their opinion as to the nature of that tumour. Dr. Purser thought it an example of an epithelial growth, while Dr. Richardson, probably examining a different portion, thought it an enchondromatous growth. These are thus exceedingly difficult and obscure matters, that are perplexing to the most skilled microscopist. It was better to begin with the most simple forms, and therefore every case he brought forward that night was of the simplest form, about which it was not likely any competent microscopists would differ. The observations of Dr. Purser on Thiersch's hypothesis were interesting, and coincided with his own view. His illustrative case was a tumour in the mammary gland, there the various structures existed so closely and intimately intermixed (as completely as wool and silk in a piece of tabinet) as to be absolutely inseparable. Still, they might use Thiersch's theory as a basis of classification with great utility from the point of view Dr. Corley had spoken of, namely, to give the student some idea of what are the true bases of classification of tumours. For that purpose it was quite invaluable. They could give an idea that all tumours in which a morbid form of epithelial structure vastly predominates are connected with the outer layer, while those in which the connective tissue vastly predominates come from the middle layer. If it were for nothing more than this as a basis of classification it was of importance; for all they could hope to do was to group these tumours according as particular structures predominate in them. He thought classification most useful for the instruction of student, but for practical purposes it was entirely useless.

Dr. KENNEDY read a paper on

THE STRENGTH OF MUSCLE,

which we shall give in our next issue.

MEDICAL SOCIETY OF DUBLIN.

At the meeting on February 10, Dr. HENRY KENNEDY, Vice-President, in the chair,

Mr. H. R. SWANZY (by permission of the Council) made a communication to the Society on

THE SIGNIFICANCE OF "CONGESTION PAPILLA," OR "CHOKED DISC," IN INTRA-CRANIAL DISEASE.

After alluding to the interest of the subject for the physician, and describing the appearance presented by congestion papilla, or choked disc, and the modes of production, he said that every observer admitted that intra-cranial tumours gave

rise to congestion papilla, and he thought most would at least allow that it was the most frequent cause of this appearance. With regard to meningitis as a cause of congestion papilla, he was of opinion that the true congestion papilla dependent on any form of meningitis is extremely rare at any time of life, and that when it does occur it is almost always in the meningitis of children, or young children. The number of published cases in which meningitis produced choked disc was very small. Von Graefe was evidently of opinion that a less pronounced form of congestion papilla was sometimes found in cases of meningitis. He (Mr. Swanzy) had examined five or six children with symptoms which were considered indicative of meningitis. In all but one of those cases the ophthalmoscopic appearances were either negative or consisted merely in the congestion of the central vein of the retina, with some hyperemia of the disc. In one case, a child of about five years of age, the appearance was different: at first it seemed to be a true congestion papilla; the optic disc was very much swollen, the central vein greatly engorged, the artery thin; the colour of the tumefaction, however, was of a deep, dusky red, and had none of that grey tint or semi-translucent appearance, and although rather prominent, its sides in no direction were very steep, but became gradually bevelled off to the plane of the retina. The patient was, however, unfortunately, removed from his observation whilst the disease was at its height. That case suggested the thought that perhaps some of the cases described as congestion papilla with meningitis were not cases of true congestion papilla, but of this other form which resembled it. It was a fact recognised by many writers that it was sometimes by no means an easy matter to decide whether a given case was one of congestion papilla or of descending neuritis. He thought it should never be attempted to make a diagnosis by aid of the ophthalmoscope unless the appearances were so well marked as to admit of no doubt as to their nature. In conclusion, he was of opinion that while true congestion papilla was not pathognomonic of intra-cranial tumours, it was extremely rare as a symptom of any other intra-cranial disease. Its value as a symptom of cerebral tumour was even greater in adults than in young people.

Dr. M'SWINEY wished to know if there were any mode by which the situation of an intra-cranial tumour might be surmised during life—whether at the surface, in the interior, or at the base of the brain?

Mr. SWANZY said it would never be possible to say by optical appearances in what part of the brain the tumour was situated. If the tumour involved some of the cranial nerves, and thereby produced symptoms of paralysis, its precise locality might be correctly surmised.

Dr. GERALD F. YEO then read a paper on

THE PATHOGENY OF HÆMORRHAGIC INFARCTION OF THE LUNGS.

The conclusions at which he arrived in the course of a lengthy communication were that the commonest cause of hæmoptysis in cardiac disease is pulmonary infarction produced by embolism; the occlusion of a vessel by an embolus fully explained the anatomical characters of the infarction and the occurrence of hæmorrhage; that the origin of the embolus may usually be traced to the cavity of the right side of the heart, where fibrinous clots are frequently formed *intra vitam*; that the alteration in the capacity and strength of the right side of the heart was commonly the immediate cause of the embolism; that disease of the smaller branches of the pulmonary artery was commonly associated with the change in the right side of the heart, and was an important agent in regulating the amount of the hæmorrhage which took place; that bleeding from the bronchial mucous membrane could not produce or even simulate true hæmorrhagic infarction; that valvular disease of the left side of the heart was a very common starting point of all those pathological changes; but that such disease was by no means an invariable concomitant of pulmonary apoplexy.

Dr. PURSER did not think that it was physiologically impossible that appearances such as those described as pulmonary apoplexy could be produced by blood being drawn into the air-cells in inspiratory effort. The contrary was proved in Sir Thos. Watson's case, in which the appearance was found after death by suffocation caused by hæmorrhage from the lingual artery, and entrance of blood into the air-passages, and in which there was no reason to suspect em-

bolism, although he (Dr. Purser) fully admitted the explanation given by Virchow of the pathogeny of the hæmorrhagic nodule to be the true one. Dr. Purser held that the theory of Sir Thos. Watson was applicable to some instances.

After some observations from Dr. Nixon,

Dr. YEO said he did not think that Sir Thomas Watson had brought forward sufficient proof that the hæmorrhagic infarctions in his case did not depend on embolus. In that case there was no difficulty in finding a source for emboli, for surely the ulceration which had opened the lingual artery must have formed thrombi in the veins, which would afford ample material for the formation of small emboli.

Dr. A. W. FOOT described an interesting case of great dilatation of the stomach, consequent upon narrowing of the pylorus, the result of an ulcer situated in the neighbourhood. It occurred in a country boy, nineteen years of age, and was characterised by periodical vomitings of large quantities of acid fermenting liquid, rich in sarcinæ. The patient derived much relief from the washing out of the stomach with alkali water, and died apparently from an attack of subacute peritonitis, for which, however, there was no obvious cause, and which did not appear to be in any way attributable to the use of the stomach-tube.

Dr. M'SWINEY asked Dr. Foot whether in the course of his treatment he had tried charcoal, as there were several instances where large doses of charcoal had rapidly produced decided relief of the flatulence consequent on dyspepsia. He would also like to hear Dr. Foot's experience of bismuth, which was vaunted as being of the greatest value in arresting a tendency to gastric disturbances where acid secretions were poured out; and finally, he wished to know whether the patient had suffered from that excruciating and torturing pain which was generally attendant on cases of persistent distension of the stomach.

Dr. FOOT said he had used neither charcoal nor bismuth, because he thought the probable cause of suffering was paralysis of the stomach from distension. The patient did not suffer very great pain, his principal suffering being from heartburn, and the pain and annoyance due to it.

The Society then adjourned.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 17, 1875.

THE METROPOLITAN SUNDAY FUND.

In our issue of last week we were barely able to do more than present our readers with the briefest abstract of the doings at the Mansion House on Monday week. The public were summoned by the Lord Mayor to receive the Report of the Special Committee appointed to revise and determine the system of distribution for the year 1875. As, however, the meeting was packed by the noisiest set of people we ever remember to have seen congregated in the Egyptian Hall, and who, as our daily contemporaries truly said, "exhibited a violence of feeling rarely

equalled," Dr. Mackenzie and his friends of the Golden Square Throat Hospital succeeded to their hearts' content in thrusting their views and resolutions down the throats of the more respectable portion of the meeting. In fact, so great was the hostility exhibited towards all the speakers on the side of the Committee that anything like fair discussion was out of the question, and it was only when the Lord Mayor threatened to leave the chair and dissolve the meeting that order was restored and a hearing secured for the occupants of the platform.

It is humiliating to reflect upon this wanton exhibition of feeling, and think it should in any way have emanated from a member of the medical profession. It is indeed sincerely to be regretted, because very many of the staunchest supporters of the Hospital Sunday Fund were driven from the meeting in disgust, and towards the end Bishop Claughton stated his conviction that very many ministers would cease to advocate the cause if Dr. Mackenzie's proposed alterations to the mode of distribution were carried. Nothing daunted, however, the cabal did its best to destroy a movement which we, in common with those who feel the deepest interest in the success of hospital work, have much at heart.

Dr. Mackenzie firmly believes in his mission to demonstrate to the contributors of the Hospital Sunday Fund, and for the encouragement of his Golden Square friends, how impossible it is for nine noblemen and gentlemen to act with impartiality and good faith in its distribution. In his opinion a Jonah is among them, and the medical element must be thrown overboard to keep the ship from sinking. The committee appointed to consider the question of distribution is "exceedingly unfairly constituted." "Three members of special hospitals to nine belonging to general hospitals" is too monstrous to be thought of. "Wranglers" predominated over sensible men; and the chief among them was Mr. Durham, and therefore "all the Committee did was to negative his scheme!!"

No wonder that to Dr. Mackenzie's perturbed mind the term "reasonable" should appear vague and unsatisfactory, and convey "permission to exercise favouritism and encourage jobbery." That he should also have found a new definition for "hospital" is by no means more remarkable. A hospital, in his belief, is a place not for the cure of patients, but one in which "patients usually die early," while, on the other hand, a home for incurables is "a place where people live long." He therefore thought incurable hospitals should participate in the Hospital Sunday Fund; it has never occurred to Dr. Mackenzie that "incurable hospitals" are not hospitals at all in the sense he attaches to them, but well-to-do charities, into which the least deserving among the unfortunate are admitted by a most objectionable system of voting and jobbery, and from whence the more urgent cases are excluded. Dr. Mackenzie declared that he merely brought forward his distribution scheme "in the spirit of conciliation." If this were so, why so much trouble to secure the attendance of people who, it is well known, never before evinced the smallest interest in the Hospital Sunday Fund, and who, it is concluded, never in any way contributed to its success?

Of Dr. Morell Mackenzie's seconder, it is sufficient to say he is a "British Incurable," a friend of the Mr. Fry who drove Dr. Chapman from his post of Physician to the Metropolitan Free Hospital last year; not for any just cause, or that Dr. Chapman had in any way failed in his duty to the charity, or in his care of the patients, but because, in all honesty of purpose, and in perfect good faith, he protested against the grossest mismanagement of the hospital affairs, and refusing "obsequious mutism," dared to direct public attention to the unfair and inadequate amount of the funds bestowed upon the sick poor in comparison with what is lavished upon managers and wire-pullers. But the story of the Metropolitan Free Hospital has been told *ad nauseam* by the medical and lay press, never more graphically, perhaps, than by a Governor in the columns of our contemporary the *Pall Mall Gazette*, who denounced it in the severest terms as "a sham." This writer fully exposed a misleading system adopted by the committee of advertising attendances of patients, and publishing them to the world as "new cases," thus "trying to make capital," while their "hospital accounts are so managed as to be unintelligible." Is there, then, any difficulty in believing that the Distribution Committee of the Hospital Sunday Fund could make nothing of them? Mr. Hood's last attempt to unravel the mystery is even less explicit and intelligible, although he offers us what he calls "a refutation of the injurious charges against this hospital (the Metropolitan Free) contained in the Report of the Hospital Sunday Fund." He, however, takes good care to avoid the charge of "extravagant management," that is, of an expenditure of upwards of 34 per cent. of the subscriptions upon secretary, office clerks, collectors' poundage, printing, and advertising. Pool-pooling all such small matters, he, with the greatest self-complacency, compares the doings of the Metropolitan Free Hospital with some of the largest, particularly with those of the London Hospital, and which in truth is about as puny as would be an attempt to compare the strength of a mouse to a horse or an elephant. In common fairness he ought to have shown, in a tabulated form, the work of the "Farringdon," the "Islington," the "Western," and a dozen other dispensaries and small hospitals, and then it would have been clearly seen that all do a larger amount of good, and relieve a greater number of patients with a tenth part of the income of the Metropolitan Free Hospital. We earnestly trust the Distribution Committee of the Hospital Sunday Fund will not yield to Dr. Mackenzie's cabal, but will persevere in its legitimate attempts to put down abuses and shams which, under the name and disguise of either hospital or dispensary, have too long been permitted to prey upon the charity-giving public of this metropolis.

THE DUBLIN HOSPITAL SUNDAY FUND DISTRIBUTION.

HAVING endeavoured, in our issues for the 17th and 24th of February and the 3rd of March, to lay before the public and the profession the inequalities and the imprudence of the present system of distribution of the Dublin Hospital Sunday Fund, it remains for us only to

recapitulate the facts to which we have called attention, and to sum up the conclusions at which we have arrived. We have therefore prepared the two following tables, which illustrate, without the confusion of the facts by unnecessary statistics, the points to which we have drawn attention. The first table institutes a comparison between the actual "work done," the actual services rendered by each hospital to the sick poor exclusive of ordinary dispensary relief, and the sums granted by the Hospital Fund Council to each institution.

Comparative statement of the work done by each participating hospital, and the money granted from the Fund in return for that work.

(Tabulated in sequence according to the amount of the grant.)

NAME OF HOSPITAL.	Work Done.			Grants from Fund.		
	Beds Maintained.	Extern Acdts.	Extern Mid-wifery.	For Work Done.	For Sub- scription.	Total.
City of Dublin	53	Record.	Nil	£ 408	£ 752	1,161
Rotundo ...	43	Nil	98	126	280	407
Mercer's ...	48	2,182	Nil	141	246	387
Sir P. Dun's ...	43	624	523	88	246	335
Steevens' ...	126	1,466	105	114	197	312
Coombe ...	17	Nil	1,224	69	146	215
Cork Street ...	42	Nil	Nil	26	94	121
St. Mark's ...	16	96	Nil	23	36	60

A perusal of this table will prove to the comprehension of our readers that under the present distribution system there is no relation whatever between the services rendered to the sick poor by any institution and the money granted to it in return for that work. Indeed, it would seem evident that the hospitals which receive least do the largest share of work, and those to whom the great bulk of the Fund is handed over do comparatively little. It is necessary to explain that the grants for "work done," set down in the fourth column of the above table, are assessed by the Hospital Fund Council *not* in proportion to the total number of beds maintained by any hospital, but upon the beds maintained by its *subscription income*. For example, if an hospital maintains 50 beds altogether, 40 of which are kept up by Government grants or by private property, and 10 are sustained by private subscriptions, that hospital will receive a grant from the Fund in consideration only of the 10 subscription beds, to the entire exclusion of the others from the calculation. Thus it happens that the City of Dublin Hospital receives £408 for its work done and Steevens' only £114, because almost the whole of the beds in the City of Dublin (39 out of 53) are maintained out of "subscription" income, while only a very small proportion (11 out of 126) are maintained in Steevens' from the same source. It will thus be seen that the "subscription" hospital (which has already received two-thirds of the entire Fund in consideration of its subscription income) receives for its "work done" a share which is also fixed in proportion to its subscriptions, and bears, therefore, no ratio whatever to the services rendered to the sick poor, and thus, instead of obtaining a fair share of the grant according to its usefulness, it is favoured with a subsidy from the Fund, five-sixths of which is a premium for effective begging and one-sixth in consideration of medical relief of the destitute.

Our second table is intended to illustrate the proportion of the income of each institution which goes directly to the patient side by side with that portion which is spent upon officials and other "establishment" expenses.

Comparative statement of the expenditure upon the patient and upon the establishment. Also of the allocation of each £1 granted from the Fund to each institution.
(Tabulated in the order of the cost of each hospital per bed maintained.)

NAME OF HOSPITAL.	Beds Maintained.	Expenditure per Bed.		Extern Patients.	Proportion of each £1 expended.	
		On the Patient.	Total.		On Maintenance.	On Establishment.
Cork Street ...	42	£ 23	£ 88s	Nil	s. d. 5 3	s. d. 14 9
Sir P. Dun's ...	43	37	70	624	10 7	9 5
Rotundo ...	43	22	63s	Nil	6 5	13 7
Coombe ...	17	16	50	1,224	4 11	15 1
City of Dublin	53	20	46	No	8 8	11 4
Mercer's ...	48	18s	44	Nil	8 4	11 8
Steevens' ...	126	23	41	1,466	11 2	8 10
St. Mark's ...	16	18	20	96	Nil	9 6
Incurables	152	20s	29	Nil	14 1	5 11

In the compilation of the foregoing table we have endeavoured to separate (in the statistics published by the Council) the expenditure upon maintenance and upon establishment in Mercer's, Sir Patrick Dun's, and the City of Dublin—the hospitals which receive no Government grant. It is but justice to Sir Patrick Dun's to point out that though we have been obliged to tabulate it in our first table as one of the most expensive of the Dublin hospitals, it would appear, if the statistics are reliable, that the greater part of its income is spent upon the patient.

The outlay upon the occupant of the bed appears to be as much as £37 a year, while that in the Coombe is only £16, in Mercer's £18 10s., in the City of Dublin £20, and in Steevens' £22.

We are not prepared to say that there is anything praiseworthy or advantageous in spending upon the patient in one hospital a sum which will keep two patients in another; but it is at least satisfactory to observe that the £70 expended per bed in Sir P. Dun's is not absorbed, as elsewhere, by useless salaried officials.

We again invite the attention of each of our readers to the fact that their hardly-spared contribution of £1 to public medical charity may, under the present system, be handed over to Cork Street Hospital, where 5s. 3d. is considerably laid aside for the patient, and 14s. 9d. for the maintenance of a stud of officers, the necessity for whom is a subject for speculation.

The gentlemen who form the Dublin Hospital Fund Council are, in the aggregate, intelligent and honourable

men of business, incapable of misappropriating a shilling of public charity for any personal feeling, or of tolerating for an instant the misuse of benevolent contributions so much wanted and so hardly procured. We have every confidence that they will give an unbiased consideration to the facts which we have endeavoured to put before them, and will, if convinced of the truth of our conclusions, act at once and decisively towards a radical reform in the system of distribution. We ask each of them whether he would wittingly contribute a shilling of charitable money except for the one great object of the relief of the deserving poor? and we submit to his judgment whether we have not proved that the method of dividing the Dub-Hospital Fund is not such as to secure its allocation to this object.

THE ARMY MEDICAL DEPARTMENT.

LITTLE more than fifteen years have elapsed since the medical schools throughout the kingdom were invited to send their students, without nomination or restriction, to compete for the appointments in the Army Medical Department.

The Warrant of 1858 had placed that service on an advantageous and honourable footing, and thus a stimulus was given to medical education by its attractions. Special classes were formed, and those who elected a military career devoted themselves assiduously to prepare for the coming struggle. There was every prospect of great mutual advantage to the army and to the profession.

Scarce half-a-dozen years had gone when disquieting rumours of infringement of the Warrant and curtailment of its privileges passed from the medical officers to their intended successors in the schools, and notes of warning soon culminated in the voice of appeal. Many changed their intentions, and the lists of candidates became smaller and smaller, till at length the numbers fell so low that the authorities had conceded, and all but published a restoration of the abstracted rights. The news spread through the schools, and quickly more than half a hundred applicants came to accept the appointments on the old terms; but the printer had not committed his employers, and, the vacancies once filled, the manuscript was rescued and destroyed.

The old victims spoke hard things of the new dupes, and blame was freely cast; while those from whom justice had been almost wrung enjoyed their triumph. By that one act a great evil had been wrought; a whole generation of medical officers had been robbed of all confidence in official honour, and driven to irreparable distrust. Since then a sad condition has prevailed: something granted, something removed; a trifle yielded, a more than equivalent curtailed; and so, with gradually descending fortune, the unequal fight has been maintained till chronic agitation has become the established atmosphere of the Army Medical Department.

And now again the open disregard of all rights of contract has brought the matter so far within the understanding of civilians that the press and the profession have raised a cry of "shame," and scared the coming students from the department's doors, so that the last examination could only draw eleven candidates, not all of

whom were able to obtain even the minimum of marks required to qualify for appointment; yet, in the face of this, the Secretary of State, on introducing the Army Estimates, says, with reference to the Medical Department, "I am not prepared to make any definite proposal on this subject;" and because certain advantages have been recently conceded to the Naval Medical Department, "that also has prevented me from arriving at a definite conclusion." Surely there never was a more striking example of the old saying, "live horse and you will get grass;" five-and-thirty unfortunate medical officers who have entered, some the fifteenth, and others the sixteenth year of service, have to continue to drag on a cheerless existence in the lowest grade till Mr. Hardy recovers from the "sudden startling" produced by the munificence of the Admiralty Warrant and sees through the maze of conflicting systems some way out of the hopeless block in promotion.

Under such circumstances we cannot conceive any young surgeon so destitute of a career as to embrace the Army Medical Department.

Notes on Current Topics.

Irish Pharmacy Proposals.

NOTHING has yet been heard of Sir M. H. Beach's promised Irish Pharmaceutical Bill, and speculation is still hot as to whether it is to be the English Bill, the Dublin Hall Bill, or the Bill of the Committee of the House of Commons. The *Pharmaceutical Journal* says that a deputation from the Society of Chemists and Druggists of Ireland has recently waited on Sir Dominic Corrigan, in reference to the subject of pharmaceutical legislation for Ireland, and at a special meeting of the Society, held for the purpose of receiving a report from the deputation, the President said that the deputation was cordially received by Sir Dominic, and that the matter in question was fully discussed. Sir Dominic also expressed the opinion that if the ranks of pharmacists in Ireland were to be augmented, it must be from the body of chemists and druggists. The journal of the English Pharmaceutical Society, although somewhat lukewarm upon the proposal to extend the operation of the Society to Ireland, is decisive in its view of the state of Irish pharmacy and the responsibility of the Irish Apothecaries' Hall for such a condition. It says: "We have always held, moreover, that it would be highly conducive to the interests of the public at large, as well as of pharmaceutical practice, if the obsolete *regime* of the Apothecaries' Hall of Ireland, in regard to pharmacy, were superseded, and if the competently qualified chemists and druggists of the sister country were permitted to perform the functions they are well able to perform, in dispensing medicines with advantage to themselves no less than with convenience to the public. The dearth of provision for the requirements of the public in this respect seems unquestionable, for it is unequivocally admitted by all parties, and we see no other means of providing for the deficiency than the removal of those

disabilities which now prevent the educated chemist and druggist from doing the work he is well able to do. We heartily concur with Sir Dominic's further recommendation that Irish pharmacists should act independently in this matter by establishing an independent Irish Pharmaceutical Society or College of Pharmacy, complementary to the existing Colleges of Physicians and Surgeons, and we have nothing to urge against the opinion he expressed that Ireland should have its own Pharmaceutical Society."

The "Nurse and Midwife" Diploma of the Dublin College of Physicians.

In the month of January of last year we sounded a note of warning on behalf of the profession in Ireland with reference to an incursion into the Irish College of Physicians by the ladies who had failed to establish a lodgment in Edinburgh. At that time a lady holding the M.D. of Zurich applied to the College to have that degree accepted as exempting her from the first half of the professional examination for the L.K.Q.C.P.

This proposal was submitted to an ordinary business meeting of the Fellows, and although the advocates of the lady's request avowed that it was only preliminary to an application for examination for the diploma, the request was at once granted by a majority of those present.

At a succeeding meeting of the College it was decided by a large majority of the Fellows not to admit females to the Licence in Medicine; but at the same time a lady who held no qualification at all—acting, it is said, under the advice of a leading Fellow—addressed a letter to the College, inquiring whether it was competent to confer the midwifery diploma of the College on women. To this a reply was returned to the effect that the College had already done so, and was ready to do so again.

Having searched for the precedent thus acted upon, we found that on the 3rd of February, 1696, the first licence in midwifery ever conferred by the College was granted to "Miss McCormack," who seems to have been the only woman ever licensed by the College.

This last act of the Fellows present involved, as we then said, a more serious consequence than their previous one, for it was a direct official pledge that they would place a registrable qualification at the disposal of the female students. Any candidate holding the midwifery diploma of the College may claim, under the 15th section of the Medical Act, to have it placed upon the Medical Register, and will thus at once become a legally qualified practitioner, and entitled under the 31st section to practise "medicine or surgery, or medicine and surgery," though only qualified in this one branch. But subsequently the College decided not to give a registrable midwifery diploma, but a certificate of competency as a midwife and nurse, which they were prepared to confer on the following terms:—

Qualifications: Age to be not less than twenty-one years; certificates of character. Preliminary examination: Reading, writing, and arithmetic. Course of instruction: Six months' attendance on systematic lectures on midwifery, and not less than six months' attendance on bedside instruction in a lying-in hospital or mater-

nity recognised by the College. Subjects for the examination: Midwifery (not including operations) and nurse-tending. Examination fee: One guinea. Form of midwife's licence: *We, the President and Fellows of the King and Queen's College of Physicians in Ireland, having duly examined A. B. in midwifery and nurse-tending, and having found her to possess a competent knowledge of the same, do hereby license and authorise the said A. B. to exercise the calling of a midwife and nurse-tender.*

This diploma, it will be observed, was carefully phrased, so as to confer a certificate of competency to act as a midwife without giving any right to register as a medical practitioner, which the usual midwifery diploma of the College would convey. By this movement the opinion of those who desired to see carried into effect the power of licensing women which was originally given to the College was satisfied, while the encroachment of the party who wished to make that function a means of admitting females to medical practice was defeated. It remained a subject of doubt whether the College had really power to grant this diploma, but until the question was legally raised it should continue to do so.

We understand that a Miss Greenstreet applied last year for this licence, and it was granted to her after examination, and following up the course which would appear to have been intended, an application has been made to Mr. Hawkins, the Registrar of the Medical Council, to have the diploma registered under the Medical Act, it being contended on behalf of the claimant that, inasmuch as the diploma was one specially provided for by the charter of the College, and issued upon the authority of a former precedent, it was entitled to registration. In this juncture Mr. Hawkins applied to the College for information as to whether they regarded the licence as a registrable qualification, but the College declined to express any opinion *pro or con.*, and thus the matter stands for the decision of the Medical Council under the advice of its law officers. Two questions arise—firstly, as to the competency of the College to grant such a diploma; secondly, as to the competency of the Medical Council to register it, assuming the power of the College to issue it.

The 15th clause of the Medical Act of 1858 declares that "Every person becoming possessed of any one or more of the qualifications described in the Schedule (A) to this Act, shall, on payment of a fee, not exceeding five pounds, be entitled to be registered on producing to the Registrar of the Branch Council the document conferring or evidencing the qualification or each of the qualifications in respect whereof he seeks to be so registered."

There is no clause in the Act to enable the Medical Council to add any qualification to those set down in Schedule (A), and as the list does not contain the diploma in question, we cannot see how the demand for registration can be sustained.

Vivisection.

PROF. DALTON, of New York, has written a monograph upon "Experiments on Animals as a means of Knowledge in Physiology, Pathology, and Practical Medicine," containing many opinions of celebrated medical men on this important question. Dr. Moquin-Tandon, who is a

member of the Institute of France, of the Parisian Society for the Protection of Animals, and Professor of Natural History in the Faculté de Médecine of Paris, observes: "Experiments upon living animals are indispensable to physiology. The truth of this statement cannot be seriously questioned. The results which have been derived from vivisection are numerous, and we appeal, in confirmation of this fact, to all physicians, surgeons, and naturalists." Dr. Parchappe, Member of the Académie de Médecine, and Inspector-General of Prisons and Lunatic Asylums, says: "For these reasons I may say confidently that experiments upon living animals is an element indispensable to the true method of study in the biological sciences." Dr. Jules Béclard, Assistant Professor of Hygiene in the Faculté de Médecine, says: "It is needless in this assembly to prove that, of all the means at the disposal of physiology, experiments on living animals is that to which science is indebted for its greatest progress. The most important and fundamental discoveries could not have been made without it. If you are interrogating life, it is vitality alone that can reply."

Dr. Piorry, Professor of Medicine in the Charité Hospital of Paris, says: "Medical practice at the present day is founded on the known facts of physiology, as applied to pathology and clinical medicine. Now, a man must have read nothing, not to acknowledge at once that vivisection has been the point of departure, or at least the most positive means of discovery for the functions of the human body." M. Boulet, Member of the Academy, and Professor at the Veterinary College of Alfort, says: "It cannot be questioned, by anyone competent to judge, that vivisections constitute means of investigation by the aid of which physiology has been taken out of the realm of dreams and conjectures, and definitely placed upon the sure basis of observation." Dr. Gosselin, Professor of Clinical Surgery in the Faculté de Médecine, says: "I believe with MM. Béclard, Bouvier, Piorry, Vernois, and Bouley, that no one can dispute the utility of vivisection, and that courses of experimental physiology should be encouraged, since they multiply the means of scientific inquiry."—*Bulletin de l'Académie de Médecine*, tome xxviii.

It is curious that the occasion of the above remarks was a memorial addressed to the French Government in 1863 by the London Society for the Prevention of Cruelty to Animals, wherein it was alleged that much cruelty to animals was caused in France by the processes of vivisection. The matter was referred by the Government to the Academy of Medicine, and the Academy, after the discussion, declared by an unanimous vote that the complaints were without just foundation.

Coffee Adulteration.

We recommend the following extract from the *National Food Reformer* to the notice of Mr. Sclater-Booth, and will be glad if he will make himself acquainted with a few of the "usages of trade" which he desires to legalise:—

Coffee is adulterated with chicory, roast wheat, peas, beans, acorns, mangel wurzel, sawdust, tea, Venetian red, and baked horses' livers. In the East-end of London exists a class of people who live by baking horses' and bullocks' livers; these are afterwards ground into a powder,

and the coffee is sold to low coffee-house and coffee-stall keepers. There are few London coffee-stall keepers who do not use this article, and on this point the writer has made most particular inquiry. It is, however, fair to say that this substance is scarcely ever in coffee bought from shops. It is said to make the coffee "go further." Coffee so adulterated, if allowed to stand until cold, will be found to have a thick pellicle or skin formed upon the top. Coffee in many cases becomes so altered and reduced in colour and appearance by adulteration, that the use of colouring matter is frequently necessitated. The favourite colouring matter is burnt sugar, known in the grocery trade as "Black Jack." This has by energetic speculators been described as a "coffee refiner," but is really employed to impart colour and bitterness to beverages made from sophisticated coffee.

When slightly moistened and squeezed in the hand, pure coffee does not agglomerate, but on the pressure being removed, it falls again to powder, whereas an adulterated article may be rolled into a ball of a more or less cohesive quality.

Slowness of Pulse.

MR. PUGIN THORNTON lately brought before the Clinical Society a case in which the pulse had at one time beat only 16, and for some weeks did not reach higher than 24 per minute. The patient was a young married woman, upon whom, in 1872, Mr. Thornton performed tracheotomy for syphilitic laryngitis. Her pulse at the time of the operation was 40, and it was not until six weeks later, when the tracheotomy-tube was removed, that the extraordinary slowness of her pulse was noticed. This infrequency had been accompanied by transient attacks of an epileptiform character. It appeared that, in the summer of 1870, she was first seized with these fits, which at that time happened daily for about two months, the pulse averaging about 24 pulsations per minute. The woman, at the present time, is in good health, her pulse being constant at 48; but she is still periodically obliged to take iodide of potassium to stop the recurrence of the laryngitis, which occasionally threatened. Mr. Thornton could not account for the curious phenomena, unless that the pneumogastric nerve might be presumed to be in some way affected by the specific poison. It was remarked by Mr. Callender that in some cases of slowness of circulation the patient seemed to suffer from cold; but he had a patient recently in St. Bartholomew's who had a pulse of 32 only, whilst a more robust man there could not be. Another member stated that in one of the earlier volumes of the *Medico-Chirurgical Transactions* there was a case recorded in which the pulse ranged from 25 to 7. At the post-mortem the foramen magnum was so contracted that it would hardly admit the tip of the little finger; and there was hypertrophy of the superior cervical ganglion of the sympathetic nerve. Dr. Symes Thompson remarked that the late Mr. Hodgson had a pulse which rarely exceeded 32; and used to draw attention to the fact that a slow pulse might exist for years without the production of any manifest symptom. Dr. Southey asked whether Mr. Thornton had noticed that micturition was very frequent, or the quantity of urine large, as when digitalis was used, the action of the heart being very slow, the quantity of urine was often very large, the pressure on the renal capillaries being great. He mentioned that a man, aged 80, whose pulse had always been slow, usually from 18 to 20, and rarely reached 26 after exertion, had noticed

the slowness for many years. Mr. Mahomed had taken sphygmographic tracings of a very slow pulse in a woman. The systole was not prolonged; but the diastole was much prolonged. Her pulse had been 65 before she was shut up in Paris during the siege, to which she attributed the change. Weakness, tendency to fainting fits, and the slow pulse had since ensued, the fainting being, perhaps, due to emptiness of the vessels of the brain. Dr. Archibald Hewan said twenty years before his pulse was 72. After great study it was found to be 55; from that point it had gradually decreased. Eight years ago it was 24. Then Dr. B. Sanderson traced it with the sphygmograph. He never had a fit nor fainted, and could bear cold well. He had lately climbed a mountain several thousand feet high, and his pulse at the top was 40. His urine had not altered in any way; his digestion was very good, and he was in good health. Dr. Althaus said that Napoleon the First had a slow pulse, and always felt uncomfortable, except in the excitement of battle, when it would rise to 60. Dr. A. Hewan mentioned that he had had rheumatic fever eight years ago, when his pulse did not rise above 32. Eight weeks ago he had gout and rheumatic pains, when his pulse quickly rose to 64 and 68, and then fell slowly to 32 and 28, at which it stood at present. Mr. Thornton stated that the pulse of his patient had not before her illness been noticed to be very slow. At the time of the operation it was 40; a few weeks afterwards it was 16. There was no valvular disease in this case. He had never heard that the urine was very copious.

American Medical Legislation.

In the Senate of New Jersey, Jan. 30th, a bill was introduced providing for the establishment of a Board of Health, to consist of ten persons, to be appointed by the Governor, who shall act without remuneration, shall investigate the causes of all diseases among men and animals, and report annually to the Governor.

In Tennessee a bill is before the State Senate, providing for the establishment of a State Board of Physicians, to issue licences to all the physicians practising in the State. It provides for the establishment in each grand division of the State, of a board of regular physicians, who shall have authority to meet annually at Knoxville, Nashville and Memphis, to grant licences to physicians and fix the fees therefor, when the same are not already fixed by law; to prescribe a course of reading for those studying medicine under private instruction; to grant licences to practise particular branches of medicine or to treat particular diseases, and to grant licences to apothecaries. The bill also provides that physicians who practise medicine or surgery, for fee or reward, in violation of this act, shall be liable to an indictment and fine of five hundred dollars for the first offence, and imprisonment not to exceed three months for the second offence.

The Medical Society of London.

THIS Society held its 102nd anniversary in the new Dining Hall of the Criterion Restaurant on Monday, the 8th inst. The President, Mr. Victor de Méric, took the chair, and a large number of the Fellows and their friends sat down to a sumptuous repast. Several excellent

songs were contributed by amateurs, all of whom were Fellows of the Society, and the arrangements gave general satisfaction. During the evening the Society's Medal was presented to the retiring secretary, Mr. Woodhouse Braine, for special services, and the President took occasion to speak in terms of much commendation of the way in which that gentleman had discharged the duties of his office. The Fothergillian Medal was not awarded. The following were elected office-bearers for the ensuing session:—

President.—C. H. F. Routh, M.D.

Vice-Presidents { W. H. Broadbent, M.D., F.R.C.P.
H. Royes Bell, F.R.C.S.
F. W. Pavy, M.D., F.R.C.P.
C. F. Maunder, F.R.C.S.

Treasurer.—John Gay, Esq., F.R.C.S.

Librarian.—J. C. Thorowgood, M.D., F.R.C.P.

Secretaries in Ordinary { C. Theo. Williams, M.D., F.R.C.P.
Richard Davy, F.R.C.S.

Secretary for Foreign Correspondence.—William Cholmeley, M.D., F.R.C.P.

Orator.—Erasmus Wilson, F.R.S., F.R.C.S.

Council.

The Rev. David Bell, M.A., (Goole) M.D.	Clement Godson, M.D.
Woodhouse Braine, F.R.C.S.	John Hainworth, F.R.C.S.
John Brunton, M.A., M.D.	T. Harvey Hill, Esq.
Thomas Bryant, F.R.C.S.	Wm. McCormac, F.R.C.S.
R. Brudenell Carter, E.R.C.S.	Victor de Méric, F.R.C.S.
Sir Henry Cooper, M.D. (Hull) F.R.C.P.	W. D. Napier, Esq.
R. Farquharson, M.D.	J. H. Paul, M.D.
Joseph Fayer, M.D., C.S.I.,	J. Russell Reynolds, M.D., F.R.S.
F. J. Gant, F.R.C.S.	A. E. Sansom, M.D.
	Leonard Sedgwick, M.D.
	Alfred Wiltshire, M.D.

The Regius Professorship of Surgery in Dublin University.

THE Academic Council of the University of Dublin elected, on last Wednesday, Mr. Wm. Colles, Surgeon to Dr. Steevens' Hospital, and ex-President of the Irish College of Surgeons, to the Regius Professorship of Surgery in the University, vacant by the death of Mr. Adams. The gentlemen who expressed their readiness to accept the office were—Mr. Colles, Mr. Porter, Mr. Tufnell, and Mr. Wharton. Although we had not anticipated the choice of Mr. Colles by the Academic Council, believing that his political views might prejudice his chance of success at the hands of a Conservative elective body, yet we are bound to say that the selection is one which will be heartily approved. Mr. Colles enjoys the highest character and an extensive practice as a consulting surgeon, and as the successor of Mr. Adams will do credit to the University.

A "Perfectly Harmless" Hair Restorer.

THE *Pharmaceutical Journal* publishes an instructive case of poisoning by a hair-restorer containing a large quantity of lead. A gentleman in Glasgow, otherwise in good health, was seized with partial paralysis of the tongue rather suddenly. His medical adviser, on questioning him, found that he had been using for his hair, which was turning grey, a hair-restorer, and on the bottle being produced it was seen to be one well known in the trade. On the label it was stated that the "restorer" was perfectly harmless, being free from lead and other injurious ingredients. The patient's symptoms indicated a stage of lead-poisoning, and the label on the bottle did

not satisfy his medical man as to the harmlessness of its contents. He therefore caused some of it to be sent to Mr. John C. Hunter for examination. On examining the article it was found to consist of lead carbonate and sulphur, the total amount of the two lead salts being equal to 325 gra. in each fluid ounce of it, notwithstanding the statement on the label that the "restorer" contained no lead or any other injurious ingredient.

Paupers' Offences in England and Wales.

An account of the number of paupers who for insubordination, larceny, or malicious damage have been committed to prison from the union workhouses of England and Wales during the six months ended at Lady-day last has been issued as a Parliamentary paper. The total number of persons committed appears to have been 2,035, of whom 632, or less than one-third, were the ordinary workhouse paupers, and 1,408 were "casuals," who obtain a night's lodging and a meal or two in the vagrant wards, and then, unless stricken with illness, turn out in the morning for the day's tramp. Of the offences recorded against the paupers and casuals the return shows "refusing to work" and "destroying his clothes" to be the chief transgressions of the latter class; "returning home drunk," "absconding with the union clothes," "refractory conduct," and assaulting the inmates or the workhouse officers are the usual offences of the former class. Some of the counties are fortunate in the fewness of the offenders. In 22 unions in Cornwall and Cumberland, 5 only had between them 7 inmates who were committed, but no casuals were sent to prison. Two unions in Derbyshire seem to have been particularly afflicted with refractory casuals. Chapel-en-le-Frith sent 28 to prison, and Derby sent 30. But Middlesex is the district which these wanderers most favour. During the six months St. George's-in-the-East sent 70 of them before the magistrates, who were committed. Marylebone sent about 120. The Poplar Union Workhouse has of late years been much used as a test-house for the able-bodied London paupers generally. The committals were 42. The counties of Middlesex, Sussex, Oxford, and Derby, had the largest number of commitments; whilst Lancashire, which is one of the most densely populated, had but comparatively few of the refractory class.

The Health of Brighton.

THE Medical Officer of Health for Brighton reports on the sanitary condition of that city during the past quarter. The death-rate for that period, including residents and visitors, was 22.7 per 1,000, of which deaths 29 per cent. were children under five. Small-pox and measles have not caused a single death; and it was noticed that the deaths from enteric fever, diphtheria, scarlatina, and erysipelas were all in houses where the drains were bad.

Oxford Undergraduates.

WE rejoice to see that the authorities at Oxford are determined to try to put a stop, in as far as they can, to the expensive style of living so common among a vast number of the undergraduates, and which is so inimical to severe study and real value and virtue.

Abuse of Tobacco in America.

THE average number of cigars smoked in the United States during each twenty-four hours is 5,168,000. The tobacco users paid through importers \$6,150,060.41 gold to the government last year in the shape of import duties, and \$33,242,875.62 through manufacturers, on account of taxes.

Manslaughter by Puerperal Peritonitis.

AT Salford, on Saturday, a midwife named Marsden was charged with the manslaughter of Mrs. Carroll, a workman's wife. The prisoner had attended several cases, and in each puerperal fever had resulted. She attended Mrs. Carroll professionally, and the unfortunate woman died in a week from fever, alleged to have been conveyed by the prisoner. Another woman also died under similar circumstances. Prisoner had been cautioned by a doctor not to attend cases whilst she had fever infection about her. She was committed to take her trial.

Mr. Christopher Heath and the "British Medical Journal."

IF a medico-scientific organisation desires to indulge in the luxury of a political journal, and fails to keep it under close control, it may find itself under the necessity of submitting to the ordeal—impalatable even to an anonymous editor—of eating the leek. This process, neither dignified nor profitable, was gone through last week by the Committee of the Council of the British Medical Association at the bidding of Mr. Christopher Heath, who had been the subject of repeated and unjustifiable attacks in the *British Medical Journal*, and who resented these onslaughts with a firmness which placed the Committee in this unhappy predicament. He peremptorily demanded an apology, and the Committee were advised to give it, which the editor of the *British Medical Journal*, like the peccant French milkman, was obliged to post upon his own shop door. The following is the apology referred to, which we extract from the *British Medical Journal*:—

"The Committee of Council of the British Medical Association have had their attention directed by Mr. Christopher Heath to certain articles which have appeared from time to time in their *Journal*, and in particular to certain expressions made use of in an article contained in the issue of July 11th, 1874, having reference to the election at the Royal College of Surgeons.

"The expressions used, and the statements made in the articles referred to, are, in the opinion of the Committee, beyond the fair limits of controversy, and might be understood to reflect upon the honour, integrity, and candour of Mr. Heath.

"The Committee, under the circumstances, feel that it is due to Mr. Heath that the remarks which have given him any pain and annoyance should be withdrawn; while, at the same time, they express their sincere regret that they should have ever appeared."

THE following is the inscription on a tombstone at Fredericksburg, in America. "Here lies the body of Edward Helder, practitioner in physic and chirurgery. Born in Bedfordshire, England, in the year of our Lord 1542. Was contemporary with, and one of the pall-bearers to the body of, William Shakspeare. After a brief illness his spirit ascended, in the year of our Lord 1618, aged seventy-six."

A Lady Doctor in Boston.

WE have received news of the death of Miss Harriet Hunt, who was one of the first American women to practise the art of medicine. Miss Hunt was also the promotor of the assertion of the rights of women in a political sense; and she refused to pay taxes, declaring that she would pay no taxes so long as she was refused the exercise of the franchise. By her will she forbids her heirs to ask anything from such of her patients as are in her debt, and she leaves to the good feeling of the latter to pay or not to pay.

Revaccination of Medical Students.

ON the occasion of the recent death of M. Vallerian, an *interne* of the Paris hospitals, from small-pox, M. Besnier strongly urges that a recommendation which he made some years since should be put into force by the hospital authorities—viz., that all students, before entering upon their clinical studies, should undergo careful revaccination.

Her Majesty's Levée.

THE medical profession was well represented at Her Majesty's Levée on Wednesday last. Amongst those who had the honour of presentation were—Dr. Horace Dobell by Sir George Burrows, M.D., F.R.S.; Deputy Surgeon-General Dr. Fayrer, by the Secretary of State; Deputy Inspector-General of Hospitals, Dr. Dennis MacDonald, Staff-Surgeon Belgrave Ninnis, Dr. E. Lawton Moss, Fleet Surgeon Thomas Colan, and Dr. R. W. Coppinger, all by the Director-General of the Navy Medical Department; Mr. Walter Coulson, F.R.C.S., by Lord Elphinstone; Surgeon J. C. Lucas, Indian Army, by the Secretary of State. The following gentlemen were also present:—Surgeon-General Murray, Drs. Langdon Down, Vernon Bell, Arthur Farre, Fraser, Cape, Grigg, Jonas R. Leake, Leonard, R.N., Alexander Marsden, Alfred Meadows, Monro, R. Turke Pigott, D.C.L., Rae, Reginald Read, Louth, W. Sedgwick Saunders, L. S. Forbes Winslow.

Exemption of Chemists from Jury Service.

THE *Pharmaceutical Journal* says that there is little probability that the long-deferred hope of chemists and druggists to enjoy exemption from serving on juries will be gratified during the present Parliamentary session. On Tuesday last, in reply to a question, Mr. Lopes, who had charge of the Juries Bill during last session, said that it was not his intention to reintroduce it this session, as the causes still exist which prevented it from passing last year.

THE tenth meeting of the Ulster Medical Society will be held in their rooms, at the General Hospital, on Wednesday evening next, the 24th March, at eight o'clock. J. Fagan, F.R.C.S.I., will read notes of a "Case of Acute Inflammation and Suppuration of the Sacro-iliac Synchondrosis," and will introduce the patient. Dr. John Moore will give an account of (1) "A Case of Traumatic Emphysema," and (2) "A Case of Inguinal Hernia complicated with Undescended Testis." Dr. Scott will give the "History of a Case of Encephaloma of the Testicle," and will show the gland.

The Couchard.

DR. DIVER, of Caterham, has invented a very ingenious contrivance for exerting pressure on the abdomen and back of parturient women, which he styles the *Couchard*. It is a kind of apparatus which the woman puts on during labour, and the patient is enabled, by pulling during her pains, to give considerable pressure to the back and support to the uterus at the same time. The patient puts on a pair of connected pads, one over the back, the other over the front of the body, and then places her feet in a pair of stirrups. Through the tops of these stirrups a cord running from the handle passes so that the hands and feet act in antagonism. This tightens the cord which is attached to a soft cushioned pad over the back, which draws that pad and the one in front together and gives great relief to the patient.

Patients have expressed themselves as greatly pleased by the support this very ingeniously devised apparatus affords to them during labour. Dr. E. Diver has taken much trouble in perfecting this invention of his, and writes us that additional experience shows him how much relief it gives to many of his patients. We should mention that, by means of a strong cord attached to the handle, and pulling over the end of the bed, the patient can employ the same abdominal and back pressure comfortably whilst lying in bed. All such devices for assisting in the alleviation of suffering are highly commendable, and we wish success to Dr. Diver's *Couchard*.

Spurious Senna.

THE *Pharmaceutical Journal* considers that it is certainly not very flattering to English pharmacists to receive convincing proof of somebody's faith in their "gullibility and ignorance." It learns from the last issue of Messrs. Southall Bros. and Barclay's "Price Current," which contains some "Hints on the Selection of Drugs," that notwithstanding Professor Bentley's evident doubt of the probability of such an event, "some hundreds of tons of spurious senna are in the market at the present time, which appear to be without doubt the leaves of *Cassia brevipes*."

DR. MARY PUTNAM JACOBI (the wife of the celebrated obstetrician, Dr. Jacobi), at a recent meeting of the New York Pathological Society, temporarily occupied the chair during a presentation of a specimen by the President.

MR. ROBERT HARDWICKE, the well-known medical publisher, and brother to Dr. Hardwicke, Coroner for Middlesex, died last week from a sudden attack of paralysis, with which he was seized while travelling by rail to London from his residence at Sydenham.

IN addition to those gentlemen whose names we gave lately as candidates for the Surgeoncy of the County Dublin Prison, we understand that Mr. Croly, of the City of Dublin Hospital, will lay his claims before the Board of Superintendence. In addition to his qualification as a surgeon in extensive public and private practice, Dr. Croly puts forward a special claim on the ground of his experience of prison work, having been for fifteen months

surgeon in charge of the Spike Island Government Convict Prison and Military Depôt, and holding official testimony to his efficiency in that capacity.

We hear with much pleasure that the discussions recently held on the sanitary condition of the clerks of the British Museum are about to bear fruit, and the clerks are to be allowed to write upstairs, leaving the unwholesome ground-floor for books.

Cases of diphtheria continue to occur in families occupying the married soldiers' cottages on Woolwich Common. It is a disgrace to the nation that marriage among soldiers should be such a miserable, nay, fatal affair, as far as their offspring are concerned.

An official return gives 1,295,529 kilogrammes as the amount of horse-flesh consumed in Paris during 1874. There are now 50 horse-flesh butchers in Paris itself and five in the Banlieue.

The Shakers do not know what has become of Miss Wood, who has been liberated from the asylum. The sanitary inspector reports the tent as over-crowded, but it is not likely the guardians will interfere at present.

The Registrar-General reports that during last week, 5,781 births, and 4,495 deaths occurred in 21 large cities and towns in the United Kingdom. The average rate of mortality in these towns was 30 per 1,000.

The late Sir Arthur Helps, the able writer of "Friends in Council," and of "Companions in Solitude," has passed away from the ranks of the living. A severe pleurisy, gained in one of the levée days, was the cause of his death, which all true lovers of elegant literature will sincerely mourn.

The Surgical Society of Ireland will meet on Friday next, at half-past eight o'clock, at the Royal College of Surgeons, when the following communications are set down for reading:—Mr. Wheeler, "On the Removal of a Sewing-needle from the Pharynx by Pharyngotomy;" Mr. C. Fitzgerald, "On some Peculiar Symptoms connected with Obstructions of Lachrymal Puncta, Canaliculi, and Nasal Canals;" and Mr. H. G. Croly, "On the Treatment of Fractured Patella by Position."

ADVERTISEMENTS have been issued for a surgeon to the Co. Tyrone Infirmary, whom the Board of Governors will elect at a special meeting to be held on Saturday, the 27th of March (in the room of Henry Thompson, Esq., M.D., resigned), at a salary of £94 per annum, with residence, fuel, and light.

The surgeon and physician selected must reside in the institution, and shall discharge the duties of surgeon and physician to the Tyrone County Gaol, as same have heretofore been performed by the medical officer of the infirmary, without any additional remuneration.

The recent deputation of the hop growers to the Local Government Board, concerning the much-vexed question

as to the orthodox composition of beer, has induced the *National Food Reformer* to give a short history of the rise and progress of brewing.

When hops were first introduced from the Netherlands (for the hop is not indigenous to England), petitions were presented against their use in beer, and an act of Parliament was accordingly passed, prohibiting their use; the other ordinary bitters, such as chamomile, horehound, &c., being still continued in use. Some years later, however, another Act of Parliament was passed, legalising the use of hops, to the exclusion of all other bitters, and imposing a duty upon hops. The sole object of excluding all other bitters was a fiscal one, to simplify the collection of the duty.

In the year 1862 the hop duty was repealed, and the brewers were again at liberty to use any other bitters they chose, provided nothing poisonous was used. The natural consequence was, therefore, a return to the use of the bitters. We have ascertained that the following simple bitters are now used in part substitution of the hop:—Chamomile, calumba, chirata, gentian, horehound, wormwood, quassia, and sinaruba.

Next, with regard to the saccharine constituent of beer, which for many years consisted solely of malt. Doubtless the greater proportion of beer-drinkers even now cling to the idea that at any rate they get *malt* liquor.

Again, however, an Act of Parliament has completely altered the tastes of a nation, for the use of sugar has for some years been legalised as a substitute for malt. During the year 1874 nearly forty thousand tons of sugar were used to replace malt in breweries, both large and small, in the United Kingdom.

In concluding this description of the constitution of the beer of the present day, we must not omit to name the chemicals, which are, together with hop substitutes and sugar, so largely advertised by manufacturers and used by the brewing trade.

For assisting to preserve beer—Beans' "Brewing material" patented, bisulphate of lime, and finings.

We understand that the Council of the Royal College of Surgeons in Ireland have invited his Grace the Lord Lieutenant to a *conversazione* at the College, which is to be held on the 15th of April, and that His Grace has accepted the invitation.

The Queen has been pleased to appoint John Hamilton, Esq., to be Surgeon-in-Ordinary to Her Majesty in Ireland, in the room of Robert Adams, Esq., M.D., deceased. Mr. Hamilton is a Fellow of the Royal College of Surgeons in Ireland of twenty years' standing, and for many years has held the Surgeoncy of the Richmond Hospital, and of Swift's Hospital for Lunatics.

Correspondence.

IRISH INVESTIGATORS AND ENGLISH AUTHORS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is no new thing for me to come forward to protest against the persistent—I will not call it wilful—superciliousness of English writers in ignoring the works of their

Irish confrères; but I was sorely hurt on observing in your publication of the 3rd inst. how Dr. Drysdale, from whom I expected better, in his paper on the "Antecedents and Treatment of Tertiary Syphilis," so completely ignores the memory and work of the great Irish surgeon, Richard Carmichael. The Doctor quotes Bennett, Habershon, and Rose; but he may believe me when I state that to Richard Carmichael is due the fact that the profession was first led to see that syphilis was capable of spontaneous cure, and were led to understand that, though in judicious hands mercury was a useful remedy, abused as its employment had been, it was a dangerous and virulent poison, often rendering the last state of the patient worse than the first, and that its complications with the poison of the disease and natural dyscrasias of the constitution formed the most formidable combinations that could present themselves for treatment. Remembering even my own early days as a student, when the traditions of the past had not entirely passed away, I feel that Carmichael stands next to Jenner as a benefactor of the human race. Others had seen the mischief and tried to substitute milder remedies; but to the force of his genius and energy it is due that the eyes of the profession were opened to a new and better line of treatment.

It is to me also a great satisfaction to see that in the same institution where he first made his observations Irish talent is employed in clearing away the clouds that still hang over our minds in relation to the dire disease; and perhaps a study of Dr. Morgan's ably conducted experiments and closely reasoned arguments may cure Dr. Drysdale of his dualistic tendency.

I am, Sir, your obedient servant,

J. W. MARTIN.

CIRCUMCISION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I cannot help thinking that anyone who has had the least experience in circumcision, whether of Jews or Gentiles, must arrive at exactly the opposite conclusion to that of Dr. Levits, whose views on the subject you have quoted in your last issue. A very experienced operator in London has assured me that in upwards of two thousand cases he has never met with a single accident, and I can quite believe it. The conveyance of the bugbear syphilis is far less likely to be effected by the operation of circumcision than of vaccination, which latter, I presume, Dr. Levits would scarcely venture to condemn to disuse on that account. All experience, not to speak of probability, points out that the glans penis protected by a long prepuce, and irritated by the presence of retained secretions, is much more likely to be the subject of premature erections than one of which the sensibility is blunted by exposure from the earliest age; and, in fact, circumcision is frequently a radical cure for masturbation in the young. If it be true that the eastern nations are addicted to immoderate self-abuse, which I doubt, and certainly will decline to believe until certified by some more impartial witness than Dr. Levits, bent upon abolishing a practice sanctioned by an experience of close on five thousand years, we must look for the cause in the seclusion of the females of those countries; and not to the rite of circumcision, which, on the contrary, blunts the sexual appetite, and has actually been cried down on that score alone.

The operation efficiently performed is not, as experience proves, dangerous in children; it rather retards than promotes puberty, as may be witnessed any day in our midst; syphilis and gonorrhœa are of comparatively rare occurrence among the circumcised, whether born so or made. It is further incredible that an operation so dangerous should have been had recourse to continuously for so many ages without a general outcry being raised against it; but so far from this being the case, many "scientific medical men" would gladly see it extended to all children born with an elongated prepuce.

There is one part of the Jewish rite which is certainly indefensible—namely, the sucking of the wound; it is a modern innovation, useless and nasty, and urgently demanding abolition; but the operation itself is not only harmless, but decidedly salutary, and worthy of general adoption.

You do not appear to be aware of the fact which I have seen alluded to in one of your contemporaries, that Dr.

Levits is, or was, a member of the Hebrew persuasion, and has, I have no doubt, had a disagreement with the officers of his synagogue—*hinc lachrymæ*.

I am, Sir, yours obediently,

W. T. GREENE, M.B.

218 Old Kent Road, S.E., London.

COMPULSORY FEEDING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As I have lately had under my care a gentleman who continued to refuse food, I had recourse to the following method, which I have not seen described, of overcoming his obstinacy. Having had him placed upon a mattress, in the supine position, with his head unpillowed and inclined towards myself, who was seated at his right side, I introduced the first two fingers of my left hand, on the inside, and my thumb, on the outside of his right cheek. An assistant followed my example on the opposite side, while a second raised the upper lip and closed the nostrils. By a joint action between myself and my opposite assistant, the cheeks were drawn inwards, and somewhat upwards, so as to form, as it were, the sides of a cup-shaped vessel. About half a table spoonful of soup was now administered slowly, which trickled its way along the side of the right cheek towards the pharynx, which it reached through the spaces behind the last molars. At this time the patient suspended his respiration, and by a kind of gurgling endeavoured to get rid of the fluid. Efforts of this kind were of necessity unavailing, in consequence of the position in which the cheeks and lips were maintained. He was then compelled, in order to inspire, to swallow the fluid, after which he drew a long inspiration. Having allowed him a few minutes' rest, I repeated the process until he had taken a sufficient meal. Subsequent trials have satisfied me of the efficiency and safety of the proceeding I have thus briefly described, and of its superiority over the administration of food by the nostril or œsophageal tube, by neither of which is the sense of taste, an important element in the treatment, taken into consideration. I have only to add, the patient became very quickly educated, so that not only did he swallow with as much expedition as was deemed prudent, but better than this, he surrendered at discretion, and of his own accord took his meals with regularity and eagerness.

I am, Sir, your obedient servant,

J. H. WHARTON.

28 Upper Merrion Square, 12th March, 1875.

Medical Affairs in Parliament.

MEDICAL PRACTITIONERS IN THE MERCHANT SERVICE.

IN the House of Commons on Thursday last, in reply to Captain Pim, Sir C. ADDEBURY stated that a few foreign medical practitioners had been appointed to British ships under diplomas of their own country. That was under the provisions of the Passengers Act, 1855, but neither British nor foreign practitioners had, to his knowledge, been appointed to passenger ships who were not duly qualified.

PAUPER LUNATICS IN WORKHOUSES.

ON Friday, in reply to Captain Home, the CHANCELLOR of the EXCHEQUER stated that pauper lunatics in workhouses in England were not in the same position as pauper lunatics in poorhouses in Scotland. In the latter they were under the direct control of the Lunacy Commissioners; and he could not make the case of Scotland a precedent for granting aid from the Imperial Exchequer to paupers in workhouses in England.

DIPHThERIA AT WOOLWICH.

IN reply to Mr. Sheriff, Mr. HARDY stated that an outbreak of diphtheria took place at Woolwich in November last, but apparently was not confined to these cottages, and appeared in other places in a very bad form. There were some eight or

ten cases, all of which were fatal, in Woolwich town itself. In these cottages there were 35 cases, of which 15 were fatal, so that the proportion of deaths was larger in the town than in the country. The cottages in question appeared to have been built in the early part of the century, without any due regard to proper drainage or proper construction. When the first outbreak occurred he directed the army sanitary committee to make inquiry respecting these cottages, and they recommended a certain number of remedial alterations, such as turning two rooms into one, cementing the houses, and better drainage. But these changes had not been sufficient to stop the progress of this severe disease. In consequence of a recent outbreak of the disease he had directed the army sanitary committee to go down again to Woolwich and examine the property. They had been there that day, and their report was not at all favourable, and they did not recommend that the remedial works to which he had referred should be proceeded with. He intended as early as possible to remove the brigade depôts of the 49th and 50th to barracks at Warley, part of which was already occupied by married soldiers. Their removal would take place as quickly as possible, because the time had come when strong measures must be taken to deal with this matter.

HAMPSTEAD HOSPITAL FOR CONTAGIOUS DISEASES.

Mr. COOPE has given notice that he will, on the 9th of April, call attention to the proposed erection of a hospital at Hampstead, and move for a Select Committee to inquire into the Acts constituting the Metropolitan Asylums Board, and to report, with a view of suggesting any necessary alterations.

Cancer Hospital, Brompton.—The annual meeting of the governors of this charity was held on Friday last at the hospital, Mr. G. T. Hertalet presiding. The report of the committee, read by the secretary, Mr. Jupp, congratulated the governors upon the large share of public patronage bestowed upon the institution. The medical report stated that during the twelve months 688 new patients had received the benefit of the institution, of which number 311 were admitted into the wards, and 377 treated as out-door patients. The balance-sheet showed receipts of £7,101, against an expenditure of £6,948, leaving a small balance at the bankers. The reports and accounts having been received and adopted, votes of thanks were accorded to the treasurer, secretary, and the board, and to the Baroness Burdett Coutts for her kind and continued support to the hospital. The usual compliment to the chairman closed the business of the meeting.

NOTICES TO CORRESPONDENTS.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

NOTICE TO SUBSCRIBERS.—The Publishers will be glad to receive the subscriptions for the past year, 1874—£1 2s. 6d. Subscriptions in advance for 1875, at the reduced tariff of 21s. per annum, post free, are now due, and also will be thankfully received by the Publishers in London, Dublin, and Edinburgh.

SCARCER NUMBERS FOR 1874.—The Publisher will be glad to purchase clean copies of May 30, June 3, November 18, or to exchange any other numbers for them.

A. R.—You will find the question referred to on another page.
 T. S.—The person has no right to the title of Doctor.
 ISORANTS.—1. Supposing the fact to be as stated and admitted to be so by the surgeon himself, he would hardly insist on payment. 2. An action for malpractice could only succeed where there was clear professional evidence of culpable neglect or gross ignorance. 3. In those cases there is often considerable difficulty of diagnosis at some stages. The servant's own story is ridiculous.
 Dr. LAW.—Letter on "Scarlatina and Scarlet Fever" received.
 OUR INDIAN CORRESPONDENT.—Letter shall appear in our next.
 A VIOLENT ANTI-VACCINATOR.—We have been honoured by the receipt of a post-card from a man signing himself John Morison, of the British College of Health, of pill and quack medicine notoriety, on which he descants in very abusive terms upon the Vaccination Act "that this infamous law was smuggled through Parliament in the dark hours of night." This worthy does not appear to be afflicted with "a sniffing for truth," for he states that "24 per cent. of patients taken to small-pox hospitals have been previously vaccinated." Further on he invites us to read a pamphlet on the subject by the Rev. G. Carew. We have read his post-card; he ought to be grateful for this honour without asking us to read any more trash.

DR. OGILVIE WILL'S paper shall appear if possible, in our next.
 CAMBRIDGE STATE MEDICINE.—An examination in so much of State Medicine as is comprised in the functions of officers of health will be held in Cambridge in Oct., 1875, beginning on Tuesday, Oct. 5th. Any person whose name is on the Medical Register of the United Kingdom may present himself for this examination provided he is 24 years of age. The examination will be in two parts, and will comprise physics and chemistry; laws of the realm relating to public health; sanitary statistics; origin, propagation, pathology, and prevention of epidemic and infectious diseases, &c. All applications for admission to this examination, or for information respecting it, should be addressed to Prof. Liveing, Cambridge.

THE PATHOLOGICAL SOCIETY OF LONDON.—Dr. Bastian is to read a paper in the Pathological Society soon on the "Pathology of Contagion."

COMMUNICATIONS, Enclosures, &c., have been received from—Dr. Lionel Beale, London. Dr. Archibald Billing, London. Mr. Rivington, London. Dr. Ogilvie Will, Aberdeen. Mr. J. F. Shaw, Flanderswell. Dr. Matthews Duncan, Edinburgh. Dr. Greene, Peckham. Dr. Cameron, M.P., House of Commons. Dr. Pavy, London. Mr. Hayes, Aberystwyth. Prof. Humphry, Cambridge. Mr. H. Ceseley, Aylesbury. Dr. Martin, Portlaw. The secretary of the Local Government Board. The secretary of the Royal Institution. Dr. Alex. Harvey, Aberdeen. Dr. Sturgis, New York. Mr. Macle, Liverpool. Mr. Sotheran, York. Mr. Cook, Guy's Hospital. Mr. Lunn, Birmingham. Mr. Hyalop, Church Stretton. Dr. Furdon, Belfast. Mr. Gilchrist, Kilmarnock. Mr. Sprague, London. Mr. E. Lane, Kirtou. Dr. Waring Curran, The Secretary Medical Society of London. Dr. Morgan, Dublin. Our Indian Correspondent. Dr. Morton, Castleblaney. Dr. Laffan, Cashel. Dr. Langley, London. Mr. Wakefield, Metropolitan Board of Works. Ignoramus, London. Dr. W. A. Davis, Newry. Dr. Horace Dobell, London. Dr. Kent Spender, Bath. Dr. Kennedy, Dublin. Mr. Izard, London. Mr. Morrison, London. Mr. Finnegan, Abbeyleix. The Secretary of the London Hospital Sunday Fund. Mr. Baker, London.

VACANCIES.

Abbeyleix Union. Apothecary. Salary, £40 per annum. (See Advt. Bradford Infirmary. Physician. Diplomas, &c., to be sent to the Secretary, 60 Market Street, Bradford.
 Infirmary of the City of London Union. Assistant Medical Officer and Dispenser. Salary, £100, with board and lodging. Forms of application at the Office, 61 Bartholomew Close, E.C.
 Bristol Lunatic Asylum. Assistant Medical Superintendent. Salary, £80, with board, furnished apartments, &c. Applications to the Chairman of Committee, Council House, Bristol.
 Township of Manchester. Resident Assistant Medical Officer for the Poor. Salary, £150, with furnished apartments, &c. Applications to the Clerk to the Guardians, New Bridge Street, Manchester.
 Liverpool Royal Infirmary. Resident Medical Officer. Salary, £100 per annum, with board, &c. Address the Chairman of Committee.
 Worcester County Lunatic Asylum. Assistant Medical Officer. Salary, £100 per annum, with board, &c. Applications to Dr. Sherlock, at the Asylum.
 West Norfolk Hospital. Medical Officer. Salary, £100 per annum, with board, &c. Applications to the Weekly Board, King's Lynn.

MEETINGS OF THE LONDON SOCIETIES.

WEDNESDAY, March 17th.—Royal College of Surgeons, 4 p.m. Prof. W. K. Parker, "On the Structure and Development of the Skull."
 ROYAL COLLEGE OF PHYSICIANS, 5 p.m. Dr. Beale, "On Life, and on Vital Action in Health and Disease."
 THURSDAY, March 18th.—ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, "On Electricity."
 HARBESIAN SOCIETY, 8 p.m. Dr. Chesdell, "Cases of Duchenne's Paralysis" and a "Case of Morphoea Alba. Mr. Lennox Browne, "On the Treatment of Simple Catarrh of the Nose, Throat, and Ear."
 FRIDAY, March 19th.—Royal College of Surgeons, 4 p.m. Prof. W. K. Parker, "On the Structure and Development of the Skull."
 ROYAL COLLEGE OF PHYSICIANS, 5 p.m. Dr. Beale, "On Life, and on Vital Action in Health and Disease."
 ROYAL INSTITUTION, 8 p.m. Weekly Evening Meeting. 9 p.m. Dr. R. Liebreich, "On the Real and Ideal in Portraiture."
 MEDICAL MICROSCOPICAL, 8 p.m. Exhibitions of Specimens by Mr. G. Giles.
 SATURDAY, March 20.—Royal Institution, 3 p.m. Prof. W. K. Clifford, "On the General Features of the History of Science."
 MONDAY, March 22nd.—Medical Society, 8 p.m. Ordinary.
 TUESDAY, March 23rd.—Medico-Chirurgical, 8½ p.m. Ordinary.

APPOINTMENTS.

BOOKEY, T. L., L.K.Q.U.P.I., L.M., L.R.C.S.I., Medical Officer for the Hammer District of the Elm-cumers Union, Salop.
 BRAY, H., L.R.C.P.L., M.R.C.S.E., Assistant Medical Officer to H.M.'s Convict Prison, Portsmouth.
 BUNCOME, C. H., F.R.C.S.E., Medical Officer for the City of London, Union Infirmary at Bow.
 CHAMPNEYS, F. H., M.R.C.P., Medical Registrar to St. Bartholomew's Hospital.
 CROCKER, H. R., M.B., B.Sc., L.R.C.P.L., M.R.C.S.E., Resident Medical Officer of University College Hospital.
 DAVIS, WM. ALBY, M.R.C.S.E., M.D. Univ. Glas., Consulting Medical Officer for the Urban and Rural Districts of Newry.
 FRY, J. F., M.R.C.S., L.R.C.P., a House Physician to Guy's Hospital.
 GARTANG, W., M.D., M.R.C.P., a Physician to the Blackburn Infirmary.
 GODFREY, T., M.R.C.S.E., Medical Officer for No 1 District and the Workhouse of the Mansfield Union.
 HALL, F. DE H., M.D., M.R.C.P.L., a Casualty Physician to St. Bartholomew's Hospital.
 JONES, C. M., M.R.C.S., Resident Accoucheur to St. Thomas's Hospital.

LEWIS, Dr. B., Clinical Assistant to the West Riding Lunatic Asylum, Wakefield.
MELLER, C. M., M.D., M.R.C.S.E., Medical Officer for the Fylingdales District of the Whitley Union.
MOORE, N. M.B., M.R.C.P.L., a Casualty Physician to St. Bartholomew's Hospital.
NEWBY, C. H., M.R.C.S.E., L.R.C.P.L., a House Physician to St. Thomas's Hospital.
PITTS, Mr. B., Physician's Assistant at the Bethlem Hospital for Lunatics.
RICHMOND, S., M.D., M.R.C.S.E., Medical Officer of Health for the Northallerton Urban Sanitary District.
RIGBY, J. M., L.R.C.P.L., M.R.C.S.E., Medical Officer of Health for the Chorley Rural Sanitary District.
RING, J., M.D., M.R.C.S.E., Medical Officer for the Willesden District of the Hendon Union.
SECCOMBE, G. S., L.R.C.P.L., M.R.C.S.E., Assistant Medical Officer to the Metropolitan Asylum District Asylum for Lunatics, Caterham.
STEELE, J. W., M.D., Medical Officer to the East Dispensary, Liverpool.
TATTERSALL, W., L.R.C.P.L., M.R.C.S.E., Medical Officer of Health for the Little Woolton Urban Sanitary District.
WILLIAMS, H. D., M.R.C.S.E., a House Surgeon to Guy's Hospital.

Marriages.

FINLAY—CHALMERS.—On the 23rd ult., at St. Jude's Church, South Kensington. Wm. Alexander Finlay, M.D., Trinity, Edinburgh, to Adela Edith, fourth daughter of the late John Chalmers, of Aldbar, Forfarshire.
LEWIS—HINGSTON.—On the 23rd ult., at St. Jude's Church, Dublin. George Alfred Lewis, M.B., T.C.D., L.R.C.S.I., eldest son of the late Rev. John E. Lewis, M.A., Rector of Ardmore Glebe, Lurgan, co. Down, to Emma, eldest daughter of John Hingston, Trinity College, Dublin.
PART—NORTON.—On the 2nd inst., at St. Mark's, St. John's Wood. James Part, M.D., F.R.C.S., of 49 Camden Road, to Louisa Catherine, youngest daughter of the late Richard Norton.
STOKER—HARTEN.—On the 3rd inst., at St. Thomas's Church, Dublin. E. Nugent Stoker, Bengal Medical Staff, fourth son of Abraham Stoker, late of the Chief Secretary's Office, Dublin Castle, to Susan, third daughter of John Harden, City of Dublin Steam Company.
WELCH—GARDY.—On the 13rd ult., at St. John's Church, Lybham, Francis H. Welch, F.R.C.S. Army Medical Department, Netley, to Agnes, daughter of F. Grundy, of Cheetham Hill.

Deaths.

BARTER.—On the 27th Feb., Thos. Barter, M.R.C.S.E., of Gay Street, Bath, aged 70.
CRUMMACK.—On the 24th Feb., Henry Crummack, M.R.C.S.E., of Mickle Gate, York.
DENNY.—On the 6th Feb., John Denny, L.R.C.P.Ed., of Summer Terrace, Brompton, aged 43.
HAMILTON.—On the 7th March, at Baron Lodge, Mitcham, Thos. Wm. Hamilton, M.D., aged 54.
JONES.—On the 5th March, at Eastbourne, Surgeon-Major Juxon H. Jones, late H.E.I.Co.'s Service.
MURLEY.—On the 25th Feb., Stephen H. Murley, M.R.C.S.E., of Cheltenham, aged 68.
STENHOUSE.—On the 9th March, Alexander Stenhouse, M.D., of Dunfermline.
THOMPSON.—On the 8th March, Henry Thompson, M.D., F.R.C.S.I., late Surgeon to the Tyrone County Infirmary, aged 63.
WILLIAMS.—On the 1st March, John Williams, M.R.C.S.E., of Talarfon, aged 78.

DALLYVAUGHAN UNION, COUNTY CLARE.—MEDICINE, MEDICAL AND SURGICAL APPLIANCES WANTED.—The Board of Guardians of the above Union will, at their Meeting to be held on Thursday the 8th day of April next, consider and receive TENDERS for supplying the Workhouse, Infirmary, Fever Hospital, and three Dispensaries with Medicine, Medical and Surgical Appliances for Twelve Months, from 25th March next. The Medicines must be of the best quality, and are to be delivered at the Workhouse and Dispensaries of the Union free of carriage. All empties must be removed at the Contractor's expense. All invoices to be made out in duplicate, and to contain a number corresponding with the number in the Tender. Forms of Tender to be had on application to me (none else will be considered), and when the Contract is declared the Contractor will be required to furnish each Medical Officer with a copy of the Tender, and to enter into a bond with two solvent sureties for the due fulfilment of the Contract. No charge to be made for jars, bottles, &c.
 Sealed Tenders will be received by me up to One o'clock, noon, on the above day.

By order of the Board,
THOS. COMYN,
 Clerk of the Union.

Clerk's Office 11th March, 1875.

ROYAL DUBLIN SOCIETY.—KEEPERSHIP of the MINERALS. Applications of Candidates for the above-named Office will be received by me not later than the 24th day of March, 1875. The Salary is £100 per annum.
 The gentleman to be appointed will also be elected Analyst to the Society, and have charge of the Chemical Laboratory, at an additional salary of £50 per annum, with fees for analyses; the Scale of Fees chargeable to members of the Society being regulated from time to time by the Council.

Particulars to be had on application.
 (By order of)
WM. EDWARD STEELE, M.D.,
 Registrar.
 Kildare Street: M 10, 12, 1875.

ROYAL MEDICAL BENEVOLENT COLLEGE, EPSOM.—The name of WILLIAM BAKER BROWN having been withdrawn from the List of Candidates for Foundation Scholarships of the above-named College, his mother cordially thanks all the Governors and Subscribers who voted for him at the last two elections.
 March, 1875.

SURGICAL SOCIETY OF IRELAND.—The NEXT MEETING of the SOCIETY will take place on FRIDAY EVENING, 19th MARCH, 1875.

Chair will be taken at half-past Eight o'clock precisely.
B. WILLS RICHARDSON, F.R.C.S.I.,
HUMPHREY MINCHIN, F.R.C.S.I., } Hon. Secs.
 Royal College of Surgeons, Dublin,
 17th day of March, 1875.

ABBEYLEIX UNION.—APOTHECARY WANTED.
 —The Board of Guardians of the above Union will, on Tuesday, the 23rd instant, appoint a properly-qualified Apothecary for the Workhouse at a salary of £40 per annum.

By order,
JAMES FINNEGAN,
 Clerk of Union.

Board Room, Workhouse,
 10th March, 1875.

ROYAL COLLEGE of PHYSICIANS of LONDON.—FIRST or PRIMARY PROFESSIONAL EXAMINATION for the LICENCE.—The next Examination will commence on MONDAY, APRIL 5. Students are admitted to this Examination after the termination of the Second Winter Session of Professional Study at a recognised Medical School.

SECOND or PASS EXAMINATION for the LICENCE.—The next Examination will commence on MONDAY, APRIL 12. Gentlemen who have completed four years of Professional Study according to the College Regulations, are eligible for admission to this Examination.

Registered Medical Practitioners qualified before January, 1861, are admitted to Examination under special Bye-laws.

Candidates are required to give fourteen days' notice in writing to the Registrar of the College, with whom all Certificates and Testimonials required by the Bye-laws are to be left at the same time.

Pall Mall East. **H. A. PITMAN, M.D.,** Registrar.

ROYAL COLLEGE of PHYSICIANS of LONDON.—The next PROFESSIONAL EXAMINATION for the MEMBERSHIP will commence on Thursday, April 22.

Candidates are required to give fourteen days' notice in writing to the Registrar of the College, with whom all Certificates and Testimonials required by the Bye-laws are to be left at the same time.

Pall Mall East. **HENRY A. PITMAN, M.D.,** Registrar.

MALVERN COLLEGE.

This COLLEGE contains TWO DEPARTMENTS—the CLASSICAL and the MODERN. There is also a Preparatory LOWER SCHOOL.

There are Boarding Houses within the College Grounds, held by the Head Master and others of his Staff; a Gymnasium, &c.

Board and Tuition under 14, £80; over 14, £90. Non-shareholders pay an extra fee of £6. Special advantages for Sons of Clergymen and Home Boarders.

For further information apply to the Rev. ARTHUR FABER, M.A., Head Master, late Fellow and Tutor of New College, Oxford.

The next Term commences on Monday, the 3rd of May next.

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

PATRON:—H.R.H. THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £35 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerton are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote. Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c. can be had at the office.

40 MOLESWORTH STREET, DUBLIN,
W. O'NEILL, Secretary.

ACCIDENTS WILL HAPPEN!!

Provide against the Losses that follow by taking a Policy AGAINST ACCIDENTS OF ALL KINDS, of the

RAILWAY PASSENGERS' ASSURANCE COMPANY,
 The Oldest and Largest ACCIDENTAL ASSURANCE COMPANY.

HON. A. KINNAIRD, M.P., Chairman.

PAID UP CAPITAL AND RESERVE FUND, £160,000. ANNUAL INCOME £180,000. COMPENSATION PAID, £215,000.

Bonus allowed to Insurers of Five-years' standing.

Apply to the Clerks at the Railway Stations, the Local Agents, or 64 CORNHILL, and 10 REGENT STREET, LONDON.

WILLIAM J. VIAN, Secretary.

The Medical Press & Circular.

THE LUMLEIAN LECTURES.

ON LIFE, AND ON VITAL ACTION IN HEALTH AND DISEASE. (a)

By LIONEL S. BEALE, M.B., F.R.S.,
Physician to King's College Hospital.

LECTURE I. (continued).

Bioplasm and Formed Material.—The simple living matter of a microscopic fungus, like other forms of bioplasm, is clear, colourless, and structureless, soft, and, when growing quickly, almost diffuent. It is enclosed in a capsule of equally colourless formed material, which, however, is firm, and sometimes even hard. It varies in thickness under different circumstances. By pressure the capsule may be caused to rupture, and the bioplasm within may be squeezed out. When this simple organism is nourished, nutrient pabulum, dissolved in water, permeates the capsule of formed material, and comes into contact with the bioplasm within. The non-living matter then undergoes changes most wonderful, in the course of which it acquires the same properties and powers as the bioplasm, which already exists, possesses. The thickening of the capsule of formed material is effected by the deposition of new formed material, resulting from changes in the bioplasm upon the inner surface of the formed material already existing.

If the fungus particle is placed under favourable circumstances it will grow. The particle which is growing not only increases in dimensions, but, as already mentioned, manifests a tendency to separate into two or more parts. Sometimes the living matter exhibits little projections or diverticula from its surface, each of which, after a time, becomes detached and constitutes a separate particle,

which may grow and divide like its predecessors. Now the phenomena I have, in very few words, imperfectly sketched, —the taking up of pabulum by the living matter, and its conversion into bioplasm—the arrangement of the elements of the bioplasm prior to the formation of the formed material—the moving away of portions of the bioplasm from the rest, as occurs in the production of the buds or offsets—I hold to be *vital actions*, agreeing in all essential particulars with corresponding phenomena which occur in every known kind of living matter. These phenomena differ absolutely from any actions known to occur in any kind of non-living matter whatever. They cannot be imitated, and no actions known can be fairly said to exhibit any true analogy with them. These *vital phenomena* do not characterise the formed material, for the production of this corresponds to the death of the bioplasm. As the formed material is produced bioplasm ceases to live, and no kind of formed material can grow and transform matter and direct its forces as living matter is known to do.

Bioplasm of Bacterium.—The living matter of the bacterium is probably the lowest, simplest form of bioplasm in nature. The entire organism is so minute as to be difficult of investigation. In 1864 I carefully examined bacteria under the one-fiftieth of an inch object glass, and was able to demonstrate that, like the lower fungi, the bacterium consisted of bioplasm, with a layer of formed material upon its surface, as was proved by carefully crushing a very large bacterium while under observation. The membrane was ruptured, and not only was the bioplasm seen to escape, but it exhibited vital movements when free from its envelope.

Bacteria are for the most part elongated and of an oval form, and frequently the little staff-like particle exhibits a transverse line, or is constricted at or near the centre, indicating a tendency to divide at this point. In this way the division and multiplication of already existing particles take place. Bacteria vary much in size, some being as much as the one-three-thousandth in length, others so minute as to be visible only with the aid of the one-fiftieth of an inch object-glass. I have figured some less than the one-ten-thousandth of an inch in diameter.

The germs from which the little particles spring are far

(a) Delivered at the Royal College of Physicians on Friday, March 12th.

more minute, and more difficult to identify. They appear as minute specks, the largest of them exhibiting a circular outline, and probably being spherical. The smallest are too minute to be discerned with the highest magnifying powers at our command. If a specimen of fluid, in which these particles are rapidly growing and multiplying, be carefully examined, many new points will be observed to appear from time to time. After watching with great care for a considerable time a given spot, I have assured myself that new particles actually come into existence—not that one merely *sees* more after intently watching for a time and concentrating the attention upon a certain space, one coming into view after another, as star after star.

The material in which the minute germs of bacteria are embedded, and which, at least in part, consists of formed material produced by the bacteria, is much softer than the matter of which the capsule of fungi consists. It is perhaps almost as soft as mucus. I believe that even the most minute bacterium germ is surrounded by a layer of such soft formed matter, in which very minute particles of bioplasm divide and subdivide before they attain even the one-one-hundred-thousandth of an inch in diameter. When, therefore, bacteria, in an early stage of development, dry, it is not possible to identify them. When moistened the dry mass swells up, and the bioplasm in the soft mucus-like matter grows, each particle producing a fresh investment of formed material; and then, if the conditions are favourable, the germs either at once divide and sub-divide for a time, or grow into perfect bacteria, which move freely and grow and multiply in this more advanced stage of development.

It would be difficult to say where bacteria germs do not exist. In air, in water, in the soil, adhering to tiny particles of every kind—in every region of the earth, from the poles to the equator, they are to be found. At all periods of the year they retain their vitality. Extreme dryness does not destroy them, and they withstand a temperature far below the freezing point. Under adverse circumstances they remain dormant, and are not destroyed by a degree of heat which is fatal probably to every other living organism. Dr. Bastian tells us that living germs of bacteria are destroyed at a temperature of 160 degs., but others are of opinion that at least, under certain circumstances, bacteria germs do not die at 212 degs., and may increase and multiply after having been exposed to this degree of heat.

In the substance of the tissues—nay, in the cells of almost all plants, and in the interstices of the tissues of many animals, bacteria germs exist. I know not what part of the body of man and the higher animals is entirely destitute of particles which, under favourable circumstances, develop into bacteria. Upon the skin and the surface of mucous membranes they exist in profusion, and they abound in the mouth and in the follicles and glands. Changes in the process of digestion are soon followed by the multiplication of bacteria in every part of the alimentary canal, and within a few hours countless millions may be developed. They multiply in the secretions, under certain circumstances, almost as soon as these are formed, and I have adduced evidence to show that bacteria germs exist even in healthy blood. In the very substance of some cells I have seen them, and in many cases, in which little granules have been discerned in connection with bioplasts, there is reason to believe that some of them are really bacteria germs, passive as long as the higher life is maintained in its integrity, but ready to grow and multiply the instant a change favourable to them and adverse to us shall occur.

As the germs of bacteria are found in healthy tissues and organisms and grow and develop into bacteria when disintegration and decay occur, we shall not be surprised at their existence in disease. Bacteria prey upon morbid structures and upon the substances resulting from the death of morbid bioplasm. They are found in great number among pus-corpuscles which have ceased to live, and they grow and multiply with great rapidity in fluids which contain disease germs as soon as these begin to lose their

specific powers and to undergo decomposition. In the tissues and fluids of the body altered by fevers, they are abundant and exist, as is well known, in many instances during life. In the evacuations of cholera, and not only of cholera, they are very numerous, and in the columnar epithelium of the small intestine, I have found many. In all parts of the bodies, in the fluids and amongst the solid tissues of animals destroyed by cattle plague, bacteria were present in varying number.

Germs so minute as those of bacteria are constantly passed over, and until they have grown somewhat it is not possible to identify them. This circumstance has led some to suppose that they are really formed anew from non-living matter, or from a substance in a transition state, which is neither living nor dead. But such a view is not supported by facts at present known, nor is there anything to justify any other conclusion than that all matter is either living or not living.

Living Matter Structureless.—As far as can be ascertained by examination, under an amplifying power of 5,000 diameters, living matter throughout nature is colourless and *structureless*. Of course it may be mysteriously suggested that living matter may nevertheless possess structure though no one can see it. Water *may* possess structure, but in such a suggestion the word “structure” has a meaning assigned, different from that which is implied when the “structure” of tissues is referred to. No “structure” which can be conceived to exist in bioplasm can possibly account for its properties and actions. Neither is it in the least degree probable that, could we magnify it to any extent conceivable, any “structure” would be revealed, or that from the appearances described we should be able to explain how tissue and other things were formed from bioplasm, or why one kind of bioplasm forms dog, another sheep, and another man.

All the evidence I can collect is in favour of the conclusion that the powers of bioplasm do not depend in any way upon characters that can be fairly termed structural, and I cannot help fearing that some of my contemporaries biased by previous education and influenced by the pressure put upon them by one or two scientific authorities have consented to adopt views which, they will find, cannot be supported by facts or argument.

Not only does living matter exhibit no indications of structure, but the highest known form of living matter could not be distinguished from the lowest, and the lowest is not more unlike non-living matter than is the highest. One is, in fact, just as near and just as far from inorganic matter as the other. It has been said that certain organisms only differ from a fragment of albumen by their granular character, but the statement is not correct. In the first place a granular appearance is not characteristic of living matter. If granules are discerned in it, they are not essential and are at least as likely to be lifeless as they are to be living particles. Living matter is, in fact, as free from granules as a fragment of the purest albumen. Secondly, the differences between any fragment of albumen and any living particle are enormous—but of a kind quite distinct from that suggested in the above statement.

If a portion of pure bioplasm be carefully examined with the highest powers at our command, and under the most favourable circumstances as to illumination, it will be found to be entirely devoid of granular character. Clear, transparent and colourless, there will not be discernible in any part of it the faintest indication of structure. Nay, if motionless, its presence can only be recognised by the fact of it being a very little less perfectly transparent than the fluid which surrounds it, and by its refracting property being slightly different from that of the medium in which it lives.

The suggestion so often made that the relation between living and non-living matter is a close one, is as entirely groundless as the further suggestion that before very long the exact nature of the relation between the two will be cleared up and the chasm between the living and the non-living bridged over. Neither is there anything to justify the statements made for the purpose of inducing people to

believe that the non-living passes into the living by insensible gradations of some kind. There are many characters in which the living differs absolutely from any form of non-living matter yet discovered. One broad essential character distinctive of all living particles is a remarkable capacity of movement which has not been adequately accounted for, and I therefore propose to direct your attention to the movements peculiar to living matter.

Of Vital Movements.—Every form of living matter exhibits certain movements, the nature of which has not been determined. The remarkable movements of the common amoeba, of the mucus corpuscle, of the pus-corpuscle, and of the white blood corpuscle, are familiar examples of vital movements, and these can be seen and studied by anyone who can use an object-glass magnifying 500 diameters or upwards. But every nutritive act, every form of increase and multiplication, each kind of growth, the production of buds or offsets, the development, the formation and increase of every tissue involves active movement of the particles of which living matter is composed. Vital movements affect every form of living matter from the very lowest, supposed by some to have been formed direct from the non-living, to the very highest which is concerned in the development of man; but in certain instances only can the movement be actually seen to occur under the microscope. By very slight alteration of the conditions existing during life the movements may be caused to cease, but in many cases in which no movement has been seen, we have other evidence that it has occurred. Vital movement, there can be no doubt, accompanied the first dawn of life, and will continue to characterise living matter to the end of time. In fact, vital movements are essential. Their cessation is coincident with the cessation of life. Without them life is not conceivable; and it is equally impossible to conceive any form of matter not in a living state which manifests movements like those which characterise life.

I propose to consider the subject of vital movements under the four following heads, viz. :—

1. Vital movement which may affect every part of a mass of living matter.

2. The movement of the constituent particles of a living mass, which takes place in a direction from centre to circumference.

3. Movement of one portion of a mass of living matter from the rest.

4. The movement of a mass of living matter from one place to another.

Lastly, there are certain movements which are indirectly due to the vital movements of bioplasm such as ciliary action, some movements connected with nerve action, the movement of certain solid particles in cells, &c., but these will not be discussed here, as I desire to restrict myself, as far as possible, to the consideration of the nature of the intimate changes in living bioplasm only. Neither shall I enter into a discussion concerning the nature of "contractility," which has, by some, been considered to be vital in the same sense as the movements which I am about to describe. I have, however, adduced reasons for removing contractility from the category of vital movements. I shall, therefore, only remark that contractility as it occurs in muscle is essentially distinct from the changes now to be discussed, and I may state that I have referred to this part of the subject in my work on "Protoplasm," 3rd edition, page 209. The original paper was published in the Transactions of the Microscopical Society for 1866.

1. *Vital Movements which may affect every Part of a Mass of Living Matter.*—These movements are undulatory in character, and may be seen in many forms of living matter. The wave-like movement gives rise to continual changes in the thickness of the mass, which, as a whole, may remain quite stationary. If the margin of the mass of living matter be studied, its outline will be observed to continually alter; a slight bulge at one place, a slight depression at another. In a few moments perhaps the part which projected will recede, and that which was depressed will become prominent, but with no regularity, with no

alternation of movement. Such changes may be seen continually proceeding over every portion of a mass, in some cases occurring very quickly, in others so slowly that a specimen must be watched intently in one spot for some minutes, or the observer will fail to discern any change. In the amoeba these movements are distinct enough, and can be studied without difficulty. The matter which moves is perfectly transparent and structureless. Granules suspended in it may be moved, but they are not the cause of the movement. Wave-like movements may be seen in young epithelial cells. I have seen them in epithelium from the throat and from the bladder of man, and I think there can be no doubt that they take place in living matter generally. In the white blood corpuscle they have been studied by many. I have given a description of the movements as they occur in the mucus corpuscle and in the pus corpuscle, and have appended figures showing the changes observed during the course of a few seconds. I conceive that it is by movements of this kind that the little masses of bioplasm near the surface of the brain, which I believe are concerned in mental operations, act upon the delicate nerve fibres which are in contact with all parts of their surface. These, are, I believe, the instruments through which the will operates upon the nerve-apparatus, by which its mandates are rendered evident.

2. *Movements of the Constituent Particles of a Living Mass which take place in a Direction from Centre to Circumference.*—The actual movements referred to under this head cannot be seen, for they may take place slowly, and affect particles too small to be seen with the highest powers. But that motion in the direction indicated does occur seems to me to be conclusively proved by the fact that in some spherical masses of growing bioplasm, which are increasing rapidly, a new centre (nucleus) appears in the very centre of the mass. After this has grown for a time another new centre (nucleolus) appears in the centre of the first. The new growth originates centrally, and a newer growth still more centrally. This involves a movement of constituent particles outwards. Now if bioplasts, in which this change is actually proceeding, be coloured with an ammoniacal solution of carmine, which in some instances may be effected in a few seconds, the remarkable fact will be observed that the new centres have been stained most deeply, although these are situated at the greatest distance from the surface in contact with the coloured solution. All "nuclei" and "nucleoli" are new centres of growth, and invariably consist of living matter. An oil globule may be formed in bioplasm, and may be called a nucleus or a nucleolus, but the formation of such a body is of no importance. It ought never to have received the name of nucleus, and no one ever pretended that all nuclei were of this nature. True nuclei and nucleoli were considered of little importance, but if the evidence in favour of the view of their nature, here advanced, is correct, and I believe it to be incontrovertible, nuclei and nucleoli must be regarded as *vital centres* which have originated in centres of living matter already existing.

The movement outwards of the constituent particles of bioplasm is, I venture to think, the circumstance which determines the flow of the nutrient fluid in the opposite direction. The non-living pabulum, I think, flows to the centre of the particle of bioplasm. Certain of its constituents there begin to live, and then move outwards towards the circumference, their place being taken by new matter which reaches the centre.

3. *Movements of One Portion of a Mass of Living Matter from the rest.*—This form of vital movement can be seen without any difficulty. A bulge appears upon the surface of a mass of bioplasm. This gradually increases and becomes pear-shaped. The projecting portion of the living matter moves away from the general mass with which, however, it may remain connected for some time by a narrow pedicle. Such movement of living matter may be seen in the amoeba, in the mucus corpuscle, in pus corpuscles, and in white blood-corpuscles, and many other forms of bioplasm. The bioplasm (nucleus) of the frog's red blood-corpuscle often

completely divides into several portions, some of which I have seen make their way through the surrounding coloured material into the liquor sanguinis beyond. I have described the phenomenon under consideration as it occurs in the growth and multiplication of yeast, and also in the growth of the mycelium of fungi. What determines the precise spot upon the surface where the formation of the bud or outgrowth commences it is difficult to say. It may be that the first movement takes place where there happens to be least resistance, but certainly it does not necessarily begin at the lowest point or at the highest, or at that part which happens to be nearest to the light, or at that most distant from it. The outgrowth does not usually contain a visible new centre, but its growth soon becomes accelerated, and the rate of formation of new bioplasm in the bud greatly exceeds that of the rest of the mass.

4. *Movement of a Mass of Living Matter from place to place.*—This form of vital movement is also to be seen very distinctly, and so many instances of its occurrence have been recorded, that it must be considered an attribute of bioplasm generally. In many cases, though the movement may not be seen, the evidence of its occurrence is nevertheless most conclusive. Not only amœbæ and allied forms, destitute of locomotor organs, move actively, but many of the bioplasm particles of man and the higher animals may be seen to move from one situation to another under the microscope. The movement of entire mucus corpuscles, white blood corpuscles, and pus corpuscles, over a space equal to more than twice the diameter of the corpuscle has been seen by me many times, and I have described the phenomenon in more than one of my works.

In white fibrous tissue, in muscle, nerve, yellow elastic tissue, and some other textures, there is distinct evidence of the movement of the formative bioplasm during the formation of the tissue. In some instances I have satisfied myself that an elongated mass of bioplasm has divided longitudinally or obliquely into two parts, which have moved away from one another in opposite directions, one forming the upper and the other the lower part of the same fibre. The thickening of many fibres results from the formation of new matter from the oval mass of bioplasm as it moves backwards and forwards upon the surface. Before 1861, I demonstrated the bioplasm of yellow elastic tissue which had not been previously observed, and showed that new tissue was formed from the bioplasm as it moved over the surface of the fibre. (a) In some cases the bioplasm is prevented from moving from place to place in consequence of being imprisoned in a cavity, but it may continue to move actively nevertheless. Thus, in many plant cells the bioplasm moves round and round the circumference just within the cell wall. In many cases the direction of rotation is that of a spiral, and formed matter, produced by transformation of the bioplasm, is deposited during the movement. The result is a spiral, or double spiral raised line of secondary deposit in the interior of the cell. Sometimes bundles of fibres are formed by the movement of the bioplasm in the interior of a cell after the "cell wall" has been formed. The fibres of the cells of the cartilage of the epiglottis are produced in this way, and I have seen the bioplasm gradually tapering so as to form a delicate fibre, which seemed to have been spun off, as it were, from the bioplasm as it moved round and round the cell cavity.

Of the several primary vital movements I have described, none can be imitated. They are peculiar to living matter and not one of them has been explained by physical law. No mere physical or chemical attractions, or repulsions, on the part of any material particle at all resemble vital movements. Neither can these be adequately accounted for by attributing them to changes in the environment, for no conceivable changes outside would cause such movements. Nor is there any *machinery* in bioplasm to explain the movement.

Of the several movements of living matter, I believe

(a) "The Structure of the Simple Tissues," 1861, p. 118.

those which affect the ultimate living particles of bioplasm never cease. That moving of matter from centre which involves the movement of pabulum in the opposite direction, I believe to be an essential phenomenon of life. The movement of living particles amongst one another, the movements of a portion of a living mass from the rest, the movement of a living mass as a whole may entirely cease, but I cannot conceive the cessation of motion in a vital centre. The rate of movement certainly varies very much. At one time it may be very rapid, at another it may take place very slowly, but I cannot imagine absolute cessation of movement in the direction indicated, even for an instant, and its recurrence in that same centre.

I beg you to carefully consider the evidence upon which the views I have advanced are based. It has been affirmed that the phenomena occurring in the simplest living matter are not far removed from the phenomena of the non-living, and like these are to be explained mechanically, but only the assertion, not the explanation, is forthcoming. If but one class of these movements of living matter can be accounted for by any laws that are known, can you not insist that the laws be stated, and that it be shown precisely by what means the particles of a living mass that is alive are enabled to move in any direction with equal facility? The particles uppermost in a mass of bioplasm do not move downwards more easily than those at the lowest point move in the opposite direction, neither do the roots of the tree grow into the soil with greater force than its stem shoots upwards.

In this lecture I have shown that in all parts of all living beings, at every period of life, are numerous masses of structureless living matter. From the lowest forms of life to the highest, this living matter, or *bioplasm*, manifests certain phenomena which cannot be accounted for by physics. Among these purely *vital phenomena* I have included certain movements which have not been accounted for. These movements are *vital*, and, as I believe, due to a peculiar power, "*vitality*."

In my next lecture I shall discuss the constitution of this living matter, try to show that the distinction between it and matter in every other state is *absolute*, and endeavour to convince you that the construction of every living body is primarily due to *vital* rather than to *physico-chemical* actions.

(Lecture II. will appear in our next.)

ON THE STRENGTH OF MUSCLE. (a)

By HENRY KENNEDY, M.B.,

Physician to the Whitworth Hospital, Drumcondra; Vice-President College of Physicians, &c.

IN the following paper I would make a few remarks on the strength of muscle. I am induced to do so in consequence of certain views which have been recently advanced, and which seem to me to be very open to discussion. Prominent, if not foremost amongst the holders of these views is the name of Professor Haughton, an Honorary Fellow of your College, and, as all are aware, the author of an elaborate work on "Animal Mechanics," in which he has brought mathematics to bear on the question. With the mathematical portion of the work I have nothing whatever to do here. But the idea that the weight of a muscle is synonymous with its strength is another matter; and this idea, as far as I am aware, runs through the entire work. In truth, no other factor is noticed, and size is assumed, as I said, to be only another name for strength: that is, given the weight of a muscle, you have its strength. Now this view it is which I believe to be too narrow, and it is to invite attention to the point that I now appear before you. Not that I would underrate the size or weight of a muscle in a question of this kind; for size must be

(a) Read before the Surgical Society of Ireland, February 12. The discussion will be found at page 250.

allowed to be the leading factor ; but that I believe other factors exist, which modify, and to a very marked degree, the results which have been deduced and published in the work to which allusion has just been made.

Amongst the subjects which arise in discussing a question of this kind I may first ask your attention to that of temperament. It is no easy matter to say in what this consists. But that it exists is certain, and what is more to my present purpose, its effects are shown in a very striking way, both on the mental and physical constitution of the individual. It would be quite out of place here to enter into an account of the temperaments. I must refer you to the works which treat of them. Suffice it to say that the differences which obtain amongst individuals seem to be due to the preponderance of one or other of these temperaments, whether it be the sanguine, the nervous, or the leuco-phlegmatic, or, as it often happens, a union of the two former. I am sure all present have observed these differences, both in the mental, and possibly still more in the physical constitution of our frames. When the sanguine temperament prevails, or a union of this with any other, every movement is well known to be modified by it. Our gait, style of walking, the very way we shake hands, are all characteristic ; and when we come to look for what bears directly on my subject, I mean the class that can put forth the greatest physical strength, I think I am correct in stating that it is never amongst the largest men it is found, nor necessarily where the muscles are the most developed, but much more amongst men of medium size, and often indeed in men of a still lower stature, but who had that something in their frames which temperament, in part at least, confers. One example of this kind I may here refer to, and one whom all present knew—I mean the late Professor Smith. I recollect well the time when at putting the stone he had few or no equals, and his leaping was a sight in itself; on the whole, then, I look upon temperament as a most important element in our frames, and, whatever its nature be, capable of producing results which are very antagonistic to the idea that the greater the development the greater must be the power conferred.

In close connection with the subject of temperament the nervous supply to muscles may be mentioned. It requires no proof here of the intimate connection which subsists between the nervous and muscular systems, or how much the state of the former affects the latter. In what nervous energy consists it would be hard to say, or how it is conveyed from the brain and spinal marrow to the muscles; but that a something is carried by the nerves is certain, and in direct connection with this point it is particularly to be noted that the brain does not keep a relative size to that of the body; for it is a well-known fact that the size of the brain is not determined by that of the body. In other words, men of low stature and small frames have larger heads comparatively than those of larger frames. This I believe to be, at least, one of the causes of their greater energy and activity, as I presume all present must have observed. This point relating to the greater development of the nervous system involves questions of no little interest; amongst the rest the question of cerebral development in connection with mental power. That is what is known as phrenology. But to enter into these topics would far exceed my present limits, and so I merely advert thus briefly to them here.

Of a like kind with the last fact noticed is the size of the heart, which is known to vary comparatively but little with the size of the frame, and so it is that, bulk for bulk, small men have the largest hearts. That a vigorous circulation has much to say to the energy of the individual few, I presume, will deny (a). And this leads me on to say something of the muscles themselves; and of the voluntary kind, with which we have here to do, it need scarcely be observed that they receive, a large supply of blood. But

on this point, as you know, very considerable differences exist. In fact, animals might, I conceive, be divided into those with whitish and those with red muscles. Nearly all wild animals may be described as having dark red muscles; whilst the domestic animals, those especially which are not worked, are of a much lighter colour. But the point goes much further than this: for, as you know, the muscles in the same animal may be, and are, of different colours; and I believe this is mainly due to the greater exercise to which they are subjected. The rabbit, turkey, and other animals exhibit examples of what I mean. In ourselves, too, there are marked shades of difference, which I believe may all be referred to the one cause, that is, the more or less exercise which they get. Now, I hold that, *ceteris paribus*, the weaker the muscle the more powerful it is; and further, that wild animals are, weight for weight, much stronger than domestic ones. The arms of the gorilla—the largest that I have seen in the British Museum—are not by any means as large as those of a man. Yet it would, it seems to me, be a bold statement to say that the man's were the stronger of the two; and indeed, we have the evidence of Livingstone proving the enormous power possessed by the brute, a strength out of all proportion with the development exhibited, and, necessarily, with the weight. I believe this remark applies to all animals in a state of nature, and that large and developed as the muscles of a lion and tiger may be, this gives but the very faintest idea of what their real power is.

But in the question before us there are still other points which remain to be noticed. The structure of the muscle, by which I mean here the mode in which the fibres are arranged, has, I believe, a very great influence on their power. Thus, where tendinous fascia exist amongst the muscular fibres, their power would seem to be immensely increased. I might instance the gastrocnemii and solei, and also the temporal and masseter muscles, as examples in point. The masseter, I take it, has no rival in the body. When we look at the few fibres of which it is composed, and then call to mind its powers in ourselves, we cannot but feel that its strength is enormous. And this is shown, too, in another way. For I presume there are few who have not witnessed the feats of the gymnast, and seen the immense weight which he was able to carry on his chin. It is true the leverage of the muscle is most favourable for action; and wherever such exists, and in exact proportion with the favourable nature of the lever, will the power of the muscle in great part be. In addition, however, to this, we have in the case of the masseter the peculiar arrangement of the fibres to which allusion has just been made. So that in truth the estimation of the power of this muscle depends, it may almost be said, on other factors than the mere weight; and this remark will apply to very many other muscles of our bodies, though possibly in not so striking a degree. Speaking of the mode of arrangement of the fibres of a muscle reminds me that it is more than probable that the length of the fibres has much to say to the question under discussion. Thus I believe such a muscle as the gracilis to be comparatively weak, and that, weight for weight, it is not equal to many others, as the deltoid or triceps. This I believe to be due to the great length of its fibres; but on this point I would speak with reserve. (a)

In addition to anything which has been yet advanced, I would, as bearing on the subject before us, call attention to the effects of habit on our frames. I need not say how rapidly this habit tells upon us, and, what is of more consequence in the matter, out of all proportion with any increase of development, so that frequently one month is sufficient to enable us to overcome a difficulty which at first

(a) Independent of the length of the fibres which make up a muscle, there is another point, which, in relation with its strength, is of much more consequence; I mean the number of the fibres in a given bulk. There can be no doubt the more numerous the fibres are the greater is the power of the muscle, and so I believe that the gastrocnemius and soleus muscles are, weight for weight, more powerful than the glutens, and so of other muscles.

(a) In connection with the vigour of the circulation the development of the thorax must not be overlooked. I believe that the greater the depth and breadth of the chest the greater the energy of the individual will be.

seemed impossible. This habit is often strikingly seen in boys, and of slender make; for you may see them take up and carry with ease a trunk under which you yourself would stagger, if indeed you could raise it at all. It is certainly not development of muscle which tells here, for by much the greater weight of muscle is on the weaker side. But it is habit, or practice if you will, which has developed the power that, like latent heat, lay hid in the system. That this unusual power may be developed suddenly, and without anything of what is understood as habit, is certain. And this leads me to speak in the last place of disease as bearing on the subject under discussion. I need scarcely remind the audience I have now the honour of addressing what its effects are. In many of what are known as nervous diseases the muscles exhibit a power which is something marvellous. They will tear themselves and break the very bones. Need it be added that such occurrences take place totally independent of development of the muscles. Indeed, it may be assumed as certain that there is an inherent power in muscle, which it only requires special circumstances to bring into existence, and which is out of all proportion with the weight of the muscle. In the foregoing remarks I have alluded to some of these special circumstances, and will only recapitulate here that temperament, the nervous and vascular supplies, the differences in the muscles of wild and tame animals, the differences of muscles in the same animal, the peculiar arrangement of the muscular fibres themselves, the leverage, the effects of habit, and the results of disease—one and all seem to me to prove, beyond question, that in considering the strength of muscle there are several other factors, besides weight, to be taken into account, and that if weight alone be taken to determine the question, it can give but the merest approximation to the truth. This may be stated in other words. I believe the problem to be a very complicated one, and not yet worked out.

—◆— SNAKE-POISON.

By A. B.

Who shall decide when doctors disagree? and worse still, when journalists, the arbiters of our fame and fortune, take opposite sides, and, like lawyers, make the worse appear the better cause? These thoughts are called up by an article in the *Argus*, Melbourne, December 30th, 1874. The editor is indignant with the *Lancet* for its glaringly absurd and pseudo-scientific remarks in reference to the intravenous injection of ammonia in snake-poisoning. He says: "So long as we find that our snake-bitten may be rescued from the jaws of death by Professor Halford's mode of treatment, we may well smile contemptuously at experimental investigations, by which is demonstrated, not inferred merely, but demonstrated, 'the absolute inertness of the injection of ammonia as a remedy for snake-bite.'" But Australians are now so accustomed to hear of successful applications of Professor Halford's remedy, that the matter has ceased to excite wonder. (a) Even the medical men who have been, as we conceive, strangely and reprehensibly silent under the covert insult of the *Lancet*, have come with all classes of the people to look upon the restoration of snake-bitten persons by its means as a thing of course. The ammonia question being at last determined, "finally disposed of," as the *Lancet* intimates, we presume that all our medical practitioners, and most of the better class of bushmen, will break their syringes and spill their liquor ammonia. All decent high-minded men will be content to die placidly, *secundum artem*, as people here did die before, when bitten. None but the baser sort will flout the opinion of Fontana, of Florence, who made experiments a century ago with liquor ammonia, *swallowed* as an antidote, not injected into the veins, or will fly in the

face of "experiments made by Dr. Fayer, that really scientific investigator, who is known to have devoted himself to the discovery of what will not cure snake-bites, and is believed to have succeeded," having succeeded in killing Indian dogs, chickens, and other small animals, and a mangoose (a funny story), without attempting any antidotes, which experiments are advanced in opposition to the dozens of authenticated cases of human beings snatched from the jaws of death and poisonous snakes by Halford's venous injection of liquor ammonia. In this same copy of the *Argus* there is a fresh case of a young woman, who was nearly dead from snake-bite, from the unavoidable delay in obtaining medical assistance, but rallied immediately upon the injection of ammonia, and recovered quickly. Death takes place from snake-bites at various periods, from 25 minutes to 24 hours.

The animus of opposition was sufficiently shown by some of the auditors when for the first time, in April, 1869, Dr. Halford promulgated his treatment of snake-bite to an assemblage of the medical profession. During the debate which followed one doctor thought that injection of strong ammonia into the blood must be necessarily fatal, but he had never seen a fatal case of snake-bite (a laugh). Dr. Halford had said that there was no danger from what air might get into the vein in the operation, not even if a whole syringe were injected. A doctor said he was surprised to hear that a large quantity of air might safely be injected into the veins. Dr. Halford reminded him that the large quantity which the syringe held was half a teaspoonful (a laugh), but that he had frequently thrown that syringe into a dog with impunity. Nysten in his experiments, had found that two or three cubic inches of air rapidly thrown into a vein were necessary to kill a small dog, and from six to seven cubic inches to kill a larger dog. Again, that Majendice once threw with all the force and celerity he could, above forty pints of air into the veins of a very old horse, without his dying immediately, though he sank at last. Dr. — thought it unfortunate that the two dogs experimented upon had been allowed to die under chloroform, as it might have been interesting to see what injuries the ammonia would produce. The Professor could only remind him that it had been necessary to open the chest to record the manner in which the heart continued its action under the painless experiment, and the influence of the ammonia, and that he could assure Dr. — that he had injected many dogs with ammonia, and repeated it several times without any harm following.

An Indian experimenter on snake-bites, Dr. C. R. Francis, who does not trouble himself much about therapeutics, mentions that "A correspondent of the *Lancet* suggested that a dose of cobra-poison mixed with a glass of spirits should be given to the victim of a bite!"

Sir JAMES PAGET, Bart., F.R.S., D.C.L., LL.D.,
in the Chair.

URINARY CRYSTALS AND CALCULI; BEING OBSERVATIONS ON SOME OF THE CIRCUMSTANCES DETERMINING THE FORMS OF CRYSTALLINE DEPOSITS IN URINE, AND ON SOME OF THE CONDITIONS UNDER WHICH RENAL AND VESICAL CALCULI ARE PRODUCED.

By WILLIAM M. ORD, M.B. Lond., M.R.C.P.

1. THE starting point of the paper was the remarkable difference between the crystalline form of pure uric acid and the form of uric acid in urine; the former being in oblong

(a) Vide *Australian Medical Journal*, 1869, and a letter to the *Argus*, 25th April, 1867.

rectangular tablets, the latter in rhombohedra with rounded obtuse angles; the former in separate crystals, the latter very often in zeolitic masses. After a brief notice of former observations showing that uric acid deposited in the presence of albumen and other colloids tended to assume spheroidal form, and in the presence of sugar and other crystalloids, tabular and angular form, a series of experiments having for their object the determination of the causes of the altered form of urinary uric acid were related. The conclusions drawn from these experiments were that mucus and the colouring matter of the urine were both agents in producing the ordinary urinary form of uric acid; that either agent was capable of exerting this influence without the presence of the other; that these were probably the sole agents in ordinary urine. 2. The forms of uric acid in albuminous urine were next considered. It was remarked that, while they tended generally to sphericity, they varied much in the degree of their tendency. It was inferred from a series of observations which are related in a generalised form that a larger proportionate quantity of urea in albuminous urine constituted *pro rata* an obstacle to the sphere-forming process. 3. Two forms of uric acid were noted as occurring in sugary urine; one a flat rhombohedron, with chiselled ends; the other a side-sided tablet, with sharp ends, the latter being a rare form. 4. Purulent mucus was shown to have a great power of converting uric acid to sphericity, and of causing aggregation of spheres into calculi. Dr. Vandyke Carter's observations on the structure of calculi were referred to, and it was argued that the experiments now related agreed from the synthetic point of view with his analyses. The influence of colloids, and particularly of mucus, in favouring the formation of calculi within the urinary passages, was inferred to be of first importance, and much worthy of regard as bearing upon practice. Uric acid and other crystalline substances did not of themselves tend to form calculi, but were moulded by the other constituents of the urine. The part taken by the temperature of the body in furthering the process was discussed and regarded as important. 5. The forms of urates, and the influence upon them of chlorides, albumen, and mucus, were next noticed; mucus in a high degree, and albumen in a less degree, were noticed as favouring the formation of spheres, chiefly in association with a concentrated condition of the urine. This particularly applied to the spherical form of urate of soda observed by Golding Bird, Thudichum, Beale, Roberts, and others. 6. As to oxalate of lime, the formation of dumb-bells under the influence of colloids, already elsewhere suggested by Dr. Beale, and described by the author, was referred to, and several cases of spheroidal modifications of oxalate of lime in urine containing colloids were brought forward. 7. Triple phosphate was much less easily moulded by colloids than the substance hitherto treated. But it was shown that mucus, aided by warm temperature, could and did modify triple phosphate towards sphericity, and favour calculous deposit. And the forms obtained under such circumstances agreed in a remarkable way with the forms of triple phosphate found by Dr. Vandyke Carter in calculi. 8. The influence of albumen on the form of nitrate of urea was noted. 9. With regard to the bearing of the foregoing observations on micromorphology, it was urged that, in the microscopy of the future, beyond recording the forms of the tissues, observers would interpret the meanings of forms, compelling form to tell the story of growth and function, following out the relations between form and substance, and proceeding to the discovery of the laws of tissue-formation.

In the discussion, Dr. DICKINSON remarked that Dr. Ord had referred to uric acid as the most common centre of calculi; this statement commonly made was not correct, for he had examined numerous calculi in the London museums and found that in the majority the real centre was oxalate of lime, though it might be in small quantity. Calculi were most frequent in limestone districts, and where the water was hard, and he thought their formation probably depended on the excretion of lime in the urine, rather than on any condition of the urinary passages.

Mr. THOMAS TAYLOR said that the alteration of form of crystals described by Dr. Ord was only an illustration of the general law of crystallisation, that crystals were deprived of their angles by contact with foreign matters. Mucus was a very indefinite term, and the mucus of the bladder seemed scarcely to be the basis for the formation of calculi. He had examined numerous calculi, but had great difficulty in dis-

solving out the earthy matter without destroying the animal matter. On placing under the microscope, however, portions of the concretions found in the sturgeon (*Acipenser huso*), and treating them with nitric acid, the earthy matter was dissolved out, leaving the animal matter in the original arrangement; but he could not determine what this animal matter was. The formation of calculi might take place in some such way as the following: Long before any irritation was set up in the bladder—and it must be remembered that calculi might exist for years without producing inconvenience—the uric acid was secreted, perhaps at first in a hydrated form, after which it shrank and formed minute crystals, which became coated with animal matter, perhaps of the nature of coagulable lymph, or perhaps like the exudation under the scales in some skin diseases. Calculi were generally preceded by discharge of gravel; but a person might pass gravel for years, and yet have no calculus. He had thought it possible that in certain cases irritation took place in the kidney, where a species of inflammation was set up, leading to the secretion of fluid, and thus to the formation of calculi. He advanced this opinion, however, with some hesitation. But he believed that the formation of calculi would have to be explained by the anatomist rather than by the chemist. He recommended that, in cases of persons dying with calculus, the kidneys should be examined.

Mr. SAVORY said that the paper was interesting as pointing to the influences exerted on form. In some parts of shells there was an approximation to angular forms. Mr. Rainey had found that crystals with rounded edges were precipitated from a solution of common salt with gum.

Dr. BROADBENT remarked that Dr. Ord had given a special direction to the observations made by Mr. Rainey. Dr. Beale had found that the nuclei of calculi, apparently uric acid, consisted of oxalate of lime.

Dr. ORD, in reply, stated that he had not said that the nuclei of most calculi consisted of uric acid, but that the bulk of most calculi consisted of this. But, whatever might be the nucleus, we still had to get at an explanation of the formation of calculi. He admitted that mucus was a bad term; but it did not follow because the animal matter left after removal of the earthy matter of calculi had not the reaction of mucus, it was not originally mucus. He had been a pupil of Mr. Rainey, and thought that his observations had remained in an obscurity which they did not deserve.

HARVEIAN SOCIETY OF LONDON.

FEBRUARY 18TH, 1875.

W. H. BROADBENT, M.D., President, in the Chair.

TREATMENT OF PRIMARY DISEASES OF THE HEART.

BY J. MILNER FOTHERGILL, M.D.

DR. MILNER FOTHERGILL read a paper upon the treatment of primary diseases of the heart. He said that the successful treatment of diseases of the heart, perhaps more than that of any other class of ailments, rested upon an accurate diagnosis. It was of the utmost importance, then, to decide in each case as to whether the heart symptoms arose from some affection of the heart itself, or they were secondary, and due to some disturbance in the vascular system, standing in a causal relationship to them. The treatment of the first class of heart affections was directed to the condition of the heart itself. In the second division, the true line of practice was to remove the exciting cause, and thus to relieve the heart. The primary affections of the heart were valvular or muscular. When a valve was injured, a compensatory growth of the muscular structure usually followed. If the disease were stenosis, then hypertrophy of the muscular chamber behind the lesion enabled an equal amount of blood to be driven through a narrowed opening in an equal time—and thus perfect compensation was attained, as long as the muscular wall is structurally sound. This was best seen in aortic stenosis. Hypertrophy at other times was developed not to overcome some obstruction in front, but to limit dilatation when the muscular chambers were distended by an incoming current of blood of unwonted force. This was the case in aortic regurgitation very markedly; and was also common in mitral regurgitation when the left ventricle was distended by an inrush of blood

rom the gorged auricle and pulmonary veins. At other times the disease consisted of muscular debility, without valvular lesion. Cases were given illustrating the complete recovery of the heart from conditions of temporary dilatation. The line of treatment pursued in the cases was rest, at first, and the steady administration of digitalis and iron. The administration of digitalis might be continued for years uninterruptedly, without the production of those toxic symptoms which were supposed by older writers to indicate some cumulative action in this drug. As well as acting directly upon the heart in advanced cases with dropsical effusion, Dr. Fothergill spoke strongly in favour of the use of cathartics to relieve the venous congestion. He gave a case where two scruples of compound jalap powder were given every alternate morning, till eight doses had been taken, with excellent effects. The depressing effect of free purgation is more than compensated by the relief afforded in these cases. Digitalis and iron were also given, and the catharsis was only supplementary to the direct treatment of the heart itself. To illustrate what might be attained by such direct treatment of the heart, Dr. Fothergill adduced a case of mitral regurgitation in a young man, in whom a murmur could no longer be heard, and the subjective symptoms of disease of the heart had also vanished. Here the vela of the mitral valve were injured, and when the left ventricle was dilated, the injured valves were no longer equal to closing the ostium on the ventricular systole. The reduction of the ventricle to its normal size had resulted in the valves being once more competent; and as long as the ventricle can be maintained in a normal and undilated condition, the equivalent of a cure is attained. In mitral disease the use of digitalis is almost universally admitted, but there is less agreement as to its use in aortic disease. In Dr. Fothergill's opinion, its utility in aortic stenosis was obvious. In aortic regurgitation in the early stages, it was contraindicated, and an agent of precisely opposite qualities—one that would lessen the force of the ventricular contraction, and at the same time increase the number of beats—should be adopted, if we possessed such an agent. In the later stages, however, when the muscular walls were failing, and death threatened from cardiac syncope, then digitalis was useful as a palliative agent. Valvular disease of the right side of the heart, and especially tricuspid disease, was little amenable to treatment, because no muscular hypertrophy could be brought to bear on it. Dr. Fothergill summed up the treatment of primary diseases of the heart as follows: 1. It is of the utmost moment in these cases to reduce the demand upon the heart to a minimum. 2. Much relief may be afforded where dropsy is present, by unloading the congested venous system; and for this end cathartics are very serviceable. 3. The heart must be acted upon directly, by means of agents which increase the vigour of the ventricular contractions, of which digitalis is the chief. 4. To improve the general condition by the use of chalybeates and suitable food is also very desirable. Digitalis and iron may be continued for years, not only without any evil consequences, but with much advantage in many cases.

THE SURGICAL SOCIETY OF IRELAND.

The Society met on Friday evening, the 12th February, the Vice-President, Dr. E. HAMILTON, in the chair.

Dr. KENNEDY read a paper on

THE STRENGTH OF MUSCLE,

which will be found at page 246.

The VICE-PRESIDENT remarked that Dr. Kennedy's paper raised some very interesting questions, and brought them into the debatable land of vital force.

The Rev. Professor HAUGHTON said he had come there that evening for the purpose of hearing Dr. Kennedy's observations, and he was happy to say he concurred in at least 97-100ths of them, but he failed to get any information from the paper. There was not a single fact or datum or experiment which could enlighten him that had been brought forward by Dr. Kennedy. It was not the fashion now as much as it used to be to read the Holy Scriptures, particularly the Old Testament Scriptures but some of them might remember that when the wicked king Balak brought down the prophet Balaam to curse

Israel, the result was that the prophet blessed Israel altogether. He thought Dr. Kennedy, in making his attack on his (Professor Haughton's) book on "Animal Mechanics"—he would not say his intention was to curse the book had blessed it altogether. He would tell them the points on which he entirely agreed with Dr. Kennedy. That gentleman had laid great stress on temperament, and in that he entirely concurred. The question of temperament must modify all our experiments on muscles. He did not find, however, that Dr. Kennedy had made any, or produced any experiments, to show that white, red, and brown muscles differed from one another. He was certain they did; but they had not got from Dr. Kennedy what were the co-efficients of these different muscles. He was certain that the muscles of the wing of a grouse were different from those of the wing of a goose, or a duck, or an eagle, or from the muscles of a man. This was all summed up in the word "co-efficient," and he would be indebted to Dr. Kennedy if he would show what was the co-efficient per square inch of contractile force of the various muscles. He (Dr. Haughton) had pointed out in his book the number of fibres per square inch in a muscle. He was perfectly certain that the particular muscle, as pointed out in his book, possessed, as a result of this, if not a greater contractile force in a given contraction, a greater power of endurance. He had shown that, as the nerve supply and the blood supply of a muscle necessarily passed between the fibres, the larger the supply of fibres in an inch the greater the supply of nerve force and of blood, and the greater, consequently, the power of endurance. This particularly applied to the heart. He was sure that temperament had a great deal to do with both intellectual and muscular power, and that our mental power was not to be measured by the size of our brain vessels. Being a small man and a plucky fellow himself, he agreed with all that Dr. Kennedy had said as to the inferiority of big fellows, and no doubt all the small men in the meeting would concur with him (laughter). With regard to the gorilla, he believed he was the only person in the room who had ever dissected a gorilla, and he should like to know from Dr. Kennedy where he got the measurements he had mentioned. He had examined a skin stuffed with straw; but he was sure that it by no means represented the gorilla as he was when alive and well. He (Dr. Haughton) had compared the muscles of a gorilla with those of a chimpanzee and of a man. The thigh of the gorilla was equal to that of a man, the calf of the leg was less, and the muscles of the arm were much stronger. The gorilla had longer arms, and a greater cross-section of muscle in his arm, for a very obvious reason: Man was not intended to live by grasping his prey, but by an appropriation of his arm and hand to the higher function of the brain; and, as Professor Dawson observed, in proportion as an animal devoted its fore-limbs to the purposes of the brain these fore-limbs diminished in size, and for that reason the fore-limbs of the man were smaller than those of the gorilla. He fully agreed with all that Dr. Kennedy had said of the penniform muscles, and he had described them in his book. Dr. Kennedy had forgotten, however, the most important of all the penniform muscles, the supra-spinatus, the most characteristically penniform in the whole animal kingdom. He did not know any animal in which it was not developed. In the case of man it was a simple muscle with long fibres, but in herbivorous animals, for obvious reasons—in the ass, the horse, and the cow, for instance—it was turned into a penniform muscle. In all these matters, in the nature of muscles, temperament, &c., he could not find out where Dr. Kennedy differed from him. He now came to the small three per cent. in which they differed, and if Dr. Kennedy would only reconsider the matter, he had no doubt he would turn their ninety-seven per cent. of agreement into 100 per cent. Dr. Kennedy objected to his theory of the weights of muscles, and the reason was that he completely misapprehended the whole scope and object of his (Dr. Haughton's) book. Dr. Kennedy said that the strength of a muscle was not in proportion to its weight. He entirely concurred in that observation, and he called on Dr. Kennedy to show a single passage in his book on "Animal Mechanics" where he had confounded the strength of a muscle with its weight. In attacking this part of his theory Dr. Kennedy was not perhaps aware that he did not attack Dr. Haughton, but the celebrated Professor Borelli, professor of mathematics and anatomy in the University of Naples, who wrote a book on the subject of muscular action, which was published under the authority of the Pope more than 200 years ago. In fact, he (Dr. Haughton) had merely formulated what Borelli had laid down the data for in more modern language. Dr. Kennedy confounded two totally distinct things, and which

could not be confounded for a moment without the greatest confusion of ideas—viz., the *strength* of a muscle with the *work* done by a muscle. He (Dr. Haughton) took it for granted that the strength of a muscle meant the number of pounds pull it can give on a dynamometer or some such instrument. He had nowhere stated that the *strength* of a muscle was in proportion to its weight, but he said in the most distinct way, and he had proved it, and for 200 years no one who had made an experiment denied it, that the *work* done by a muscle was proportioned to its weight. According to Borelli's proposition, which he had tested and proved, the *vis*, or strength of a muscle, was in proportion to its cross-section, and a muscle two feet long and a square inch in cross-section would be equal in its work to a muscle one foot in length and two square inches in cross-section. Having illustrated his proposition by diagrams, Professor Haughton proceeded to say that Borelli was the first person who stated the elementary fact that was now universally recognised as the basis of animal mechanics—that the work done by a muscle is proportionate to its weight. The proposition that the work done by a single contraction of a muscle is an absolute constant rested on the basis of experiment. Experiments were made by Mr. Stanley Jevons and others of an interesting kind—such as throwing a weight, varying from 1 lb. to 14 lb., and finding what is the greatest distance you can throw the weight with a certain contraction of the muscles, and the result of these experiments had shown that the total work done by the contraction of a muscle was constant. That was the whole basis of animal mechanics, and it turned away their attention from the strength of a muscle to the work done by a muscle. When a muscle contracts a certain amount of work is given out by the body. When that was discovered by modern investigators, then they must fall back at once on this proposition, that according to Borelli the work done in a single muscle must be measured by the weight of the muscle. That rested on a basis which it was not possible to deny, and if Dr. Kennedy reconsidered the subject he would perceive the error into which he had fallen. The point once established that the work done was the thing to be measured, not the mere force of the muscle, it led to most important results. Groups of muscles could then be compared with each other in the most simple and direct manner. They could take in any animal a group of muscles doing one kind of action, and other muscles doing the same kind of work, always remembering the distinction of co-efficients, and they could compare in the most simple manner the relative amounts of work that were bestowed by nature on different actions in different animals. They had only to get the animal in a healthy condition and measure rapidly after it was killed the weights of the different groups of muscles employed in different groups of action, and they would have an universal test on which they could base different muscular types, and which would enable them to classify animals with great precision. Many Germans and Americans had taken up the idea the germ of which he had brought forward in his book, and scores of them were now weighing the muscles of every description of animal, so that after a few years the relative weights of muscles bestowed on different animals would form a part of the classification of those animals. He was glad the views he had put forward were accepted by persons who, with great respect for Dr. Kennedy, he regarded as much higher authorities on that question than he was.

Dr. HENRY KENNEDY, in reply, said it appeared to him that Dr. Haughton had given up the whole point; for he started by admitting that temperament did much, and small men were the strongest, which was in effect giving up the whole question at issue. He (Dr. Kennedy) might have mentioned many other instances of extraordinary strength in persons of small size. One gentleman of small stature, still living, he recollected when practising in Maccadd's Gymnasium, and no man could turn his arm, and he was able to raise 84 lbs. with the greatest ease. On looking at this man one would be struck at once with the size of his head; but his arm was a moderate one. He thought Professor Haughton must be mistaken in reference to the gorilla. The stuffing might be imperfect; but if it were stuffed twice the size it was it would not be the size of the arm of a large muscularly developed man; yet Dr. Haughton would not venture to say that the arm of a gorilla was weaker than the arm of a man, which was so much larger. He thought, but was not sure, it was Livingstone who mentioned that he saw the animal seize a gun and twist the barrel with the greatest ease. As to the question of the work done, (Dr. Kennedy) did not find himself tied necessarily to the amount of the work done; he believed it merely meant

endurance: but whether the work done or the brute force was to be considered, it appeared to him that the points conceded by Dr. Haughton, for he admitted that temperament and small size were modifying causes of the strength of a muscle or its endurance, amounted virtually to a giving up of the whole question. There was one point which he had forgotten to allude to: Dr. Haughton had brought forward a calculation as to the muscular power of the uterus; but Dr. Duncan, of Edinburgh, an eminent writer on obstetrics, had shown that Dr. Haughton's estimate of the power of the uterus was erroneous.

Dr. HAUGHTON rose to order. Dr. Kennedy had no right to introduce a new subject, and he was moreover inaccurate, for Dr. Duncan had admitted that the calculations referred to were correct.

Dr. KENNEDY withdrew the observation. He was glad he had brought the paper forward. It was pleasant to hear Dr. Haughton speak in his own pleasant way; but he confessed he had not disturbed his (Dr. Kennedy's) opinion as to the views which he had stated in his paper.

The Society then adjourned.

DUBLIN OBSTETRICAL SOCIETY.

THE usual monthly meeting was held on Saturday, February 13th, 1875,

Dr. LOMBE ATTHILL in the Chair.

Dr. T. MORE MADDEN read a paper on

METRO-PERITONITIS FOLLOWING THE USE OF THE ORDINARY FEMALE SYRINGE—A PLEA FOR THE VAGINAL IRRIGATOR,

in which he observed that the use of the vaginal syringe is the most common, and until recently was almost the only local treatment prescribed in uterine disorders. As this instrument is now so generally employed in all cases of real or suspected disease of the womb, that is to say, in nine-tenths of the complaints peculiar to women, and as it is freely ordered by medical men, and habitually used by patients without any special caution or apprehension of possible danger, the following case appeared to the speaker not undeserving of the consideration of the Obstetrical Society:—Mrs. W—, a healthy young lady, æt. 24, was delivered of her first child on the 16th of July, 1874. The labour, which was very tedious in the first stage, was rendered difficult by rigidity of the os uteri and malposition of the child's head, and had to be completed with the aid of the author's long forceps, an instrument of a peculiar construction, which he had elsewhere exhibited and described. After delivery her convalescence presented nothing unusual. On the 24th of August, however, she called on Dr. More Madden, complaining of pain in the back, leucorrhœa, and a distressing bearing-down sensation, which prevented her from walking, or even standing with any comfort. On examination, the os was found patulous, the uterus subinvolved and slightly prolapsed. She was ordered rest in bed, a tonic was prescribed, and she was directed to use an astringent vaginal injection. A couple of nights afterwards Dr. More Madden was sent for, but being away from home, Dr. Egan, of Talbot Street, saw her, and found that she was suffering from intense uterine colic, which had suddenly come on whilst she was using the injection before going to bed, a couple of hours previously. The local pain still continued unabated; but there was now such extreme prostration, failure of the pulse, sighing, respiration, and coldness of the skin, that, having first promptly administered stimulants and applied sinapisms over the heart, &c., Dr. Egan considered her condition so precarious that he called in the assistance of Dr. Johnston, of the Rotunda Hospital, in consultation. After some time the remedies adopted were successful in allaying the severe uterine colic and in restoring the circulation to some extent. On the following morning Dr. More Madden found her still in a state of extreme prostration, suffering from frequent paroxysms of violent uterine pain, and almost continual retching, with great tenderness over the abdomen, and especially over the uterus, which was nearly as large and hard as it should be immediately after delivery. Her pulse was 140 in the minute, and so weak that it could hardly be counted, respiration sighing, and countenance pale and anxious, and skin cold and clammy. Poultices

and anodyne stupes were applied to the abdomen, hydrocyanic draughts given to allay the retching, and her strength supported by enemata, beef-tea, and brandy. When again visited, the same evening, the sickness and uterine pain continued unabated; she was suffering from constant thirst, but no sooner did she take any fluid, or even a small piece of ice, than it was immediately rejected. She was therefore directed to take nothing whatever by the mouth, and a drop of dilute hydrocyanic acid was added to each enema. This unusual expedient, the writer observed, certainly diminished, although it did not stop the vomiting. Notwithstanding the great depression of the pulse, the local uterine inflammation was so marked that Dr. More Madden did not hesitate to apply a few leeches over the uterus, and had the satisfaction of finding that not only was the local pain thereby lessened, but that the pulse actually became fuller and less compressible than it had been before the application. A few drops of the solution of muriate of morphia were also injected hypodermically to relieve the suffering. On the following day the symptoms and treatment were almost unchanged. On the 1st of September she had slept a little during the previous night, her pulse had fallen to 120, and the uterine pain and tumefaction were diminished, although the abdomen was intensely tender, and the retching and inability to take any nourishment by the mouth continued. Dr. More Madden now had the advantage of a consultation with Dr. M'Clintock, and had the satisfaction of having his view of the case confirmed by that eminent gynecologist, who, in addition to the measures already described, suggested a trial of the oxalate of cerium in a small pill every four hours, together with "Dr. Halahan's egg-drink," to allay the incessant retching. These pills and drink in teaspoonful doses, though at first rejected, after a few repetitions were retained on the stomach, and she was better on the following day. Still, it was found necessary to continue the nutritive enemata, &c., until the 5th, when she was able to take a little iced chicken-jelly by the mouth, and from this time the symptoms gradually subsided, and she regained strength, so that a week later she sat up for a couple of hours, and was soon convalescent. In the foregoing case the uterine colic and subsequent attack of metro-peritonitis followed so immediately the use of the vaginal syringe as to leave no doubt as to their being caused by the fluid having been injected through the patulous os into the uterus and thence by the Fallopian tube into the peritoneal cavity. The possibility of an accident of this kind attending the use of the ordinary syphon syringe is practically ignored by the majority of gynecologists. Still, although such cases are comparatively rare, similar instances have been recorded by other writers; but they would appear to have made less impression on the minds of practitioners than the importance of the subject merited. Dr. Tilt says: "Only once have I been led to believe that the patient injected some portion of the fluid into the cervical canal. A lady was suffering from chronic uterine inflammation, the womb was low and slightly retroflected, the os uteri patulous, and after injecting a solution of acetate of lead, as the patient thought, in the usual way, she was suddenly seized with severe uterine pains, rigors, and intense cold. She got better when in bed by means of abdominal poultices and hot drinks, and no bad consequences followed this attack." Other cases of the same character were also quoted from Dr. J. H. Bennett and M. M. Bernutz and Goupil's works. These three references were the only allusions which the speaker was aware of to the dangers which may attend the use of the common vaginal syringe, and the paucity of similar observations appears certainly an argument that this accident is by no means frequent. Still, the mere possibility of such grave or even fatal results should render gynecologists more cautious than at present in their recommendation of that universally employed and much abused instrument. Dr. More Madden has long been impressed with the possible ill effects of the ordinary vaginal syringe, as well as the inconvenience and imperfection of this instrument. The force with which fluid is injected by it into the vagina, or even into the uterus, may, as in the case just related, be so great as to produce the most serious effects, and in all cases its action is necessarily imperfect. In order to produce any permanent benefit, for instance, in a case of congestion or inflammation of the vagina or cervix uteri, the injected fluid must be thrown against the inflamed or congested part for a long time continuously, and this cannot possibly be effected when a syringe is employed, as the fatigue of working the instrument is so great and the position of the patient is of necessity so irksome as to prevent its being used for more than a few minutes at a time. To

obviate these inconveniences various contrivances have been devised by different gynecologists. Dr. More Madden, however, still prefers the improved utero-vaginal irrigator, which he had exhibited before that Society two years ago, and a description and woodcut of which may be found in the second volume of the Dublin Obstetrical Society. With such an instrument the accident which formed the subject of this paper could not possibly have occurred, as it is merely a syphon which can be set in action or stopped in an instant at the will of the patient. This irrigator is very portable, can be readily used wherever a vessel of water can be obtained, and is capable of sending a gentle continuous stream of water, plain or medicated, and at any temperature, into the vagina, or even into the uterine cavity itself, if ever that measure, rarely required in gynecological as distinguished from obstetric practice, should be considered expedient, and this, moreover, in any position, and for any length of time that may be advisable, without causing the patient the slightest fatigue. The advantages of this irrigator over the awkward and imperfect vaginal syringe generally employed Dr. More Madden has proved in his practice during the last few years, and the comfort and benefit which his patients have derived from its use leads him to recommend gynecologists who have not hitherto employed the irrigator to give a trial to this simple, easily constructed, and easily used instrument as a substitute for the common syringe in many cases of uterine or vaginal disease. Cases such as that just related are also of some interest in their bearing on the recent discussion as to the safety of strong astringent injections into the uterus immediately after delivery in order to arrest hæmorrhage. Against this practice it has been argued that there is some danger of forcing the injected fluid through the open uterine sinuses into the circulation, or through the Fallopian tubes into the peritoneal cavity, and thus causing death, in the first case from embolism, and in the latter from peritonitis. As Dr. More Madden on a former occasion, when this subject was under the consideration of the Obstetrical Society, expressed a strong opinion as to the improbability of such an accident being thus occasioned, he now felt bound to state that the case he had related had certainly to some extent modified his views on that point. For if metro-peritonitis could be thus excited by a fluid injected into the uterus five weeks after parturition, it was of course still more possible that a similar effect might be similarly occasioned immediately after delivery, when the uterine vessels and passages were far more likely to be pervious; although such a possibility would in no degree prevent him from resorting to a remedy the value of which he had learned by practical experience in any urgent case of severe post-partum hæmorrhage which could not be otherwise controlled.

The PRESIDENT said that Dr. More Madden's paper opened up a very important subject for discussion. He did not think the occurrence of uterine colic following the injection of fluid by the ordinary syringe was so rare, inasmuch as he had had two cases of it in his own practice. Altogether he had had three cases in which uterine colic followed injection into the uterus—one following the injection of only five minims of glycerine, as recommended by Dr. Marion Sims, and it resulted in intense colic, but no peritonitis or endometritis followed. Some two years ago he was called late at night to see a patient whom he had directed to use a weak solution of borax injected into the vagina with an ordinary syringe. He found her in a state of very great collapse, and suffering intense pain over the region of the uterus, with sickness of stomach. The symptoms were soon relieved, and no inflammation followed. A less severe attack occurred in a patient who used tepid water only. He thought these cases of colic following the injection of fluid into the uterus far from being of very rare occurrence, and in several instances he had been led to desire the central hole in the nozzle of the syringe to be stopped, in order to avoid as much as possible the chance of an accident. He was not sure that the data given by Dr. More Madden carried out his theory that the fluid passed into the Fallopian tubes and thence into the peritoneum. He did not think that a stimulating fluid would be at all likely to pass through the Fallopian tubes, and he thought the phenomenon which occurred in Dr. More Madden's case could be explained on the supposition of the occurrence of a severe attack of endometritis followed subsequently by peritonitis. Exactly the same train of symptoms which Dr. More Madden had described—the prostration, the collapse, the incessant vomiting—occurred in a patient of his (the President's) where he had swabbed out the uterus with perchloride of iron. The patient was suffering from profuse hæmorrhage, occurring

some weeks after abortion; the os was patulous, and he had no difficulty in passing a pledget of cotton saturated with the styptic into the uterus; this was followed by a train of symptoms quite similar to those related by Dr. More Madden, but in this case none of the fluid could have gone through the Fallopian tubes. He (Dr. Atthill) thought Dr. More Madden right in stating that these vaginal injections, even so mild as glycerine, are not perfectly free from danger. He (the speaker) greatly preferred the irrigation which Dr. More Madden had spoken of to the use of the vaginal syringe. The President stated that recently he had acted on the suggestion of Dr. Emmett, of New York, who had carried out this vaginal irrigator very extensively. Dr. Emmett advocated strongly the vaginal irrigation with water varying in temperature from 95° to 105°. He based his treatment on the analogy that existed between the effects produced by it and an ordinary linseed-poultice, or any other hot application. The practice was to employ this douche when the patient was on her back, with her hips elevated. When they applied a poultice they found that five or six hours elapsed before the bloodless condition of the skin was produced, whereas in the case of the vagina they could not carry out the application of the vaginal douche for more than half-an-hour or forty minutes. He had also found benefit to occur from the use of cold water. In one case of chronic metritis, however, it aggravated the patient's sufferings. Before he saw her the patient had been under treatment of various kinds. He advised her to use this douche, two gallons of tepid water, temperature 105°, and in a few days she derived the most perfect relief. The great difficulty met with in using the douche was the considerable quantity of water that was requisite, rendering it necessary to empty the bed-pan every five minutes. In consequence of that objection he had recently had made a bedpan (which he exhibited to the Society) which was of the ordinary description, the only novelty it possessed being a tube attached by means of which the water was carried off. It was necessary, however, that the pan should be placed on a rigid surface. He agreed with Dr. More Madden that irrigation was better than the use of the syphon-syringe in these cases.

Dr. JOHNSTON said, that as Dr. More Madden had mentioned his name, he thought he was labouring under a mistake, as he had no recollection of seeing the patient whose symptoms Dr. More Madden had described. He (Dr. Johnston) thought that the colic might not be attributed to the mere injection into the uterus. He would rather say it must be owing to some irregularity or carelessness in her mode of hygienic treatment. At the Rotundo Hospital they frequently found in their chronic wards cases occurring of endo- and metro-peritonitis, owing to exposure to heat, but in no one instance had he found an evil result arising from the injection of cold water into the uterus. He thought the symptoms in the case stated by Dr. More Madden might be attributed just as much to the mode of the patient's living as to her having used the injection.

Dr. KIDD remarked, that with regard to uterine colic following vaginal injections, he must say that in his experience it was not a very uncommon event. Patients would use vaginal injections for weeks without suffering any inconvenience, and then it in some way happened that they got uterine colic. As a rule, it occurred almost while the patient was using the injection, but sometimes it did not take place for a considerable interval, perhaps one or two hours after the injection had been used. In one instance, at least, he had known that to occur. He had never seen it followed by an inflammatory attack. It produced a great deal of pain for the time being, and sometimes collapse, but warm applications and stimulants and anodynes generally afforded relief. It frequently occurred where the os was very patulous, and where there was a retroflexion; for the explanation of it was that the fluid got up into the cavity of the uterus and that the retroflexion prevented it returning easily. He was not prepared to say this definitively, as, as far as he knew, it had not occurred in any case under his observation where there was a retroflexion of the uterus. A very eminent gynecologist in London had stated to him in private conversation that he had never known colic to occur where warm injections were used, but generally in cold injections. He referred to Dr. Greenhall. He (Dr. Kidd) very generally recommended that the injection should not be perfectly cold.

Dr. McSWINEY said they had heard a most interesting and valuable discussion on the subject of uterine colic, but he took leave to say that he thought Dr. More Madden's paper referred to something else. He had related a case in which he

had clearly diagnosed the existence of inflammation of the peritoneum. It was very well known to most persons that the injection of various substances into the uterus might produce uterine colic. He would like to know whether it was within the experience of obstetricians that inflammation might be produced by the introduction into the vagina of an astringent lotion, or warm or cold water. The literature of the subject was, he thought, very scanty, and there were very few cases recorded where serious inflammation, extending over days, and accompanied by all the ordinary signs of peritoneal inflammation over the region of the abdomen, was produced by the use of an irritating vaginal injection.

Dr. McCLINTOCK said that the communication with which the Society had been favoured by Dr. More Madden raised a very important practical question. Everyone who dabbled in the slightest degree in midwifery thought he was perfectly safe always in prescribing vaginal injections. Dr. More Madden's case was only another instance of what they were all familiar with—that the simplest remedies, the most simple operations, and apparently the safest, would occasionally, and in very rare instances, prove highly dangerous and destructive to life. They all remembered the case of the simple operation of tapping for hydrocele, mentioned by Sir Astley Cooper, which showed that the simplest incision might be followed by the death of the patient. But such exceptional instances were not to deter them from the use of a remedy, whatever it might be, whether surgical or therapeutic. They could not say positively as to the cause in any of these cases where serious symptoms had followed the use of the injection. He did not think they could define the cause for the production of the unfavourable symptoms, because they never could say whether any of the fluid had really penetrated into the cavity of the uterus or not. It would seem highly probable that such was the case, and he would venture to say that in a case such as that brought before the Society by Dr. More Madden the circumstances were highly favourable for the entrance of the fluid into the uterine cavity, for the lady was, comparatively speaking, recently confined; it was before the uterus had regained its perfectly normal condition, and it was prolapsed. Previously he had been in the habit of telling his patients that they might use the sponge freely, and that it could not do any possible harm; but from what had fallen from others that evening, he saw that such a direction would not always be a safe one. He had, on several occasions, seen sharp, severe pain follow the use of an injection, but in every instance it was where the injection used was cold. When patients came for the first time under his notice he always told them in the first instance to use the water tepid, and gradually to reduce the temperature. He had had an opportunity of seeing the patient to whose case Dr. More Madden had been referring, and there was no room for doubt on his (Dr. McClintock's) mind that she had had a most serious attack of metro-peritonitis. The case was, he thought, a very striking one, and one that they should not let slip from their minds, but keep before their recollection.

Dr. FITZPATRICK said that in the discussion that had taken place, there had been no reference made to the kind of instrument used. The idea that they were to be stopped from the use of the ordinary vaginal injection by the fear of producing metro-peritonitis or anything else was perfectly absurd.

The PRESIDENT said he agreed with Drs. McClintock and Kidd that cold water was objectionable for vaginal injections.

Dr. DARBY said he thought it was physiologically impossible to inject fluids into the peritoneal cavity through the uterus.

Dr. MORE MADDEN, in reply, said that he had only to express his gratification that his brief paper should have led to so very interesting a discussion. The President had related cases of great importance, exactly bearing out his (Dr. More Madden's) views on the subject. The cases were very similar, with the exception that in his (Dr. More Madden's) case peritonitis occurred, and in the President's it did not. With regard to the irrigators, various descriptions had been used, and in addition to the valuable apparatus shown by the President that evening, he (Dr. More Madden) had exhibited an instrument for the same purpose two years ago, and others had done the same. With regard to Dr. Kidd's views as to these cases being caused by retroflexion of the uterus, there was no retroflexion in the case he (Dr. More Madden) had related to the Society. The uterus was carefully examined by Dr. McClintock and himself, and there was no diagnosis of retroflexion in the case. Dr. Fitzpatrick had stated that he

declined to give up the use of the vaginal syringe. Well, that was entirely a matter for his own consideration. He (Dr. More Madden) thought that Dr. McClintock had summed up what was the object of his paper—that it was simply to show that the use of the vaginal syringe was not a perfectly safe and harmless procedure at all times, and that in the majority of cases the irrigator was preferable to it. In the case before the Society the symptoms were first those of uterine colic, secondly those which were produced by some of the fluid having passed from the Fallopian tubes into the uterine cavity and leading to metro-peritonitis.

The Society then adjourned.

MEDICAL SOCIETY OF LONDON.

MONDAY, MARCH 5TH, 1875.

Dr. C. H. F. ROUTH, President, in the Chair.

ABSTRACT OF DR. ROUTH'S PRESIDENTIAL ADDRESS.

AFTER a few prefatory remarks, and after passing a high eulogium on their late President, Mr. de Méric, Dr. Routh proceeded to consider in what manner a medical mind could best regulate medical work. Referring first to the Divine attributes and character of mind, he pointed out how strange it was that amid much great and noble work done, yet the mind had in many instances fallen far short of its powers. In religion, in law, and in medicine, there were marked evidences of error, although in the end truth generally prevailed; but in the progress of advancement much violent commotion took place—in medicine especially. In tracing the causes of these, he believed, 1st, this was due to a sort of moral Darwinism in its professors, who were prepared for progressive development, but opposed to abrupt and lofty transitions. This error in natural Darwinism he exposed by giving examples of antagonisms in nature, or new platforms; and by analogy, the same had existed and would occur in medical science, of which he also gave examples. Special subjects were also minor platforms upon which a medical mind must work, and although to be preceded by general knowledge and controlled within proper limits, were evidences of progress and perfecting, and had been too violently opposed.

2nd. Another cause which had arrested progress was that we were apt to take too material a view of medical science. Facts were often material, but it was the manner in which they were used and explained which made the science. The same facts might be very differently construed. The struggle was one of *mind*, not *matter*. Hence, in the confusion some became so wedded to matter that they actually looked upon mind as matter, and thought as a cell secretion or force developed. Combating this view, he pointed out that no matter had yet developed any force akin to instinct, still less to mind. A chemical experiment was very different from a vivisection. Medicines might act very different on animals and man, on hot or cold blooded animals. Some diseases were obnoxious to animals and innocuous to man. Here were several varied platforms on which the medical mind might work. But to make anything of them at all, the power used must be mind upon the matter, and he was only successful as a practitioner who did so. He referred to the Contagious Diseases Act as tending to materialise a woman, although he admitted some moral good might incidentally be done, but feared the army and navy medical officers would themselves suffer from this materialisation, their mental being disregarded, and themselves considered as machines out of order, when proving reactive, continue to be branded as deserters and dismissed the service.

A third cause which had arrested progress was our great disregard to the discoveries of those who had preceded us.

By reference to art and architecture among the ancients, he showed how they excelled us beyond comparison. He showed that the sanitary arrangements in the way of baths of every kind was far superior to that of London, the sewers were immensely larger; the water supply better and continuous, proving that they knew that water found its own level, but preferred running water in aqueducts to underground pipes; that for a thousand years in their census they united a sanitary officer and registrar-general. They had colleges of physicians and veterinary surgeons, and even midwives.

He then referred fully to the subject of fibrinous concretions of the heart, which were discovered by Gould in 1684, and

then described by him, and by Chisholm in 1799, all forgotten till, in 1851, Dr. Richardson, one of their distinguished Fellows, had disinterred these works, and placed the disease beyond doubt, as to prognosis, diagnosis, and treatment, long before Virchow and other Continental writers had written about embolism and thrombosis.

He then referred to transfusion, originally practised on Pope Innocent, by a Jew, in 1492, and forgotten till 1865, when experimented upon by the Royal Society of England, till forbidden in France by prelates, it fell into desuetude till again revived in England by Blundell. He showed from Dr. Aveling's writings what the causes of this oblivion were, and how it was now fully recognised as a proper operation.

He next referred to the controversy on the use of the speculum vaginæ which took place in London twenty-five years ago, showing it was used in the time of Domitian, and had been found in the ruins of Pompeii, and yet had been forgotten for centuries—now it was everywhere used.

He next dwelt upon the question of cremation and burying in wicker baskets, both old customs, yet now remembered, and likely to be employed again.

A variety of obsolete practices now coming into vogue were cursorily mentioned, all of which proved we erred in neglecting ancient usages in practice, among which there were many still forgotten, which could be re-adopted with great advantage, if sought after and disinterred.

Dr. Routh concluded by a peroration pointing out the great discoveries of modern times, and looked forward to the grandest results in the future from the combined experience of the past and present.

Dr. JAGIELSKI then read a paper on

"SPIROMETRY," ILLUSTRATED BY A NEW INSTRUMENT, DIAGRAMS, AND TABLES,

a subject which has never before been noticed in this Society. After having given a definition of the word spirometry, and the various names used for the same instrument, as well as of the meaning of the term "vital capacity," or "vital volume," he detailed the origin and the gradual development of its application in physiology and pathology, paying eulogiums to the inventive and speculative mind of our great Hutchinson, whose masterly work forms a lasting and glorious monument to himself in medicine; amongst his followers he gives a long list of those distinguished in this special field, in England, Germany, France, and Holland. Then he proceeded to point out the various factors which influence the vital capacity, under normal physiological circumstances, amongst which the height, the weight, the thoracic mobility, thoracic circumference, age and sex show a certain reliable dependency for estimating the proportional and progressive value of vital capacity of men in health. In regard to the height, it is generally accepted that every inch of it causes eight cubic inches of air to be given out by a forced expiration. It is the length of both, i.e., of legs and trunk which chiefly regulates the vital capacity, and although Beizel says it seems absurd to think that the thigh and skull can exert an influence upon the air capacity of the lungs, yet it strikes me, says Dr. Jagielski, on deeper reflection, and nobody has attempted yet to explain these various facts, that physiology may give us the key to this discrepancy *par apparence*, and that the amount of blood represented by skull and legs, which necessarily must be also decarbonised and oxidised in the lungs, may explain the adequate relation, or *de facto* proportion between the height and the vital capacity. The researches of Fabius, Kuchenmeister, and Arnold were here adduced, which showed in pregnant women a much larger vital capacity on expiration than their height and thoracic circumference let suppose, in spite of the increased uterus and the pressure upon the diaphragm. The table of height and its corresponding vital capacity was here further considered and demonstrated on a diagram, as well as the weight in relation to height. Very corpulent individuals show the lowest vital capacity; they may, therefore, blow fifty cubic inches below the average, and yet have no disease of the lungs. The thoracic mobility is not constant, and according to its increase the vital capacity increases also. The thoracic circumference is not in a direct relation to the vital capacity. Age and posture have some influence, as well as a full stomach, &c. These observations constitute the "general standard" of calculating the vital capacity on an average. The "individual standard" is the more reliable way of coming to right conclusions; it consists in taking the vital capacity of the same individual at various times of his life, and in comparing its value accordingly. After an explanation of the meaning of "breathing air," complementary,

residual, and reserve air, Dr. Jagielski recommends certain rules how to obtain the quickest and highest value of vital capacity from the readings of the spirometer, the exercise of deep inspiration and expiration in a good air being beneficial to health, and tending to strengthen the lungs especially. He advises people with even very little voice and some musical ear to cultivate the singing exercise in an artistic way, as he observed himself in Italy very good effects from artistic singing in at first apparently weak-chested singers, who all felt an increased appetite directly after their singing exercise. The spirometer will show this steady improvement on the same individual by the increase of vital capacity. Under *b*. he considered the vital capacity under abnormal circumstances, and in unhealthy conditions of the body. If a man breathes at a certain time 225 cubic inches of air, and at another time he can expel from his chest but 175 cubic inches, it is evident that some cause must produce this deficiency, it may be in the lungs or it may not, but certainly the spirometer points out the deficiency. It is, therefore, the physician's duty to take up this spirometrical hint in order to come by our other means of scientific investigation, our experience and reasoning power to a positive strict diagnosis if possible. What then are the causes of this deficiency which we have to consider? They are evidently of a twofold kind; they may be general and they may be local. They may consist in a general feeble organisation or constitution, less capable of resisting the deteriorating influences to which an individual is exposed; there may be a want of muscular power in consequence of impaired general strength, and of vital power and nerve energy in some cases; or there may be a weak digestion, an impaired nutrition, and so many other functional disturbances which weaken the respiratory power; on the other hand, there may be disturbances of the mind, sorrow, anxiety, &c., which reduce physical strength, or there may be a real tendency to pulmonary consumption. Amongst the local causes we may mention flatulency, liver disease, with increased size, tumours in abdomen, &c., and in the thorax there may be congestion, inflammation of lungs, pleuro-pneumonia, pleuritic effusion, swelling of mucous membranes of bronchi, emphysema, empyema, hæmato and pneumothorax, heart disease, aneurism of aorta, intra-thoracic tumours, curvature of spine, paralysis of the thoracic muscles, &c. Special cases followed these general hints, in illustration of the valuable application of spirometry in modern times, so as to enable us to demonstrate disease when no other physical means would discover the slight changes within the lungs at this early period. Dr. Jagielski called attention also to acute military tuberculosis, a disease so little recognised in its earliest commencement and so thoroughly unmanageable and unamenable to treatment, and when once broken out in its full violence, leading so rapidly to a fatal end. He further referred to the tables appended, which showed the general vital capacity in health in relation to a certain height, and the corresponding spirometrical readings in the first, second, and third stage of phthisis pulmonalis. In proof of this he reported several prominent cases in spirometrical literature, amongst which that of the giant Freeman, as reported by J. Hutchinson, which excited much interest; this patient had lost 12 stone during his sufferings from pulmonary phthisis. Dr. Jagielski's opinion is that we should attend most anxiously and without exception to all cases where a diminished vital capacity has become evident, and the earlier we consult the spirometer and listen to its warnings the greater will be the result of our therapeutic interference, and we may in that way even be able to prevent the outbreak of disease for ever, or to delay it for many years or months. In any case, he says we shall have performed a part of our high and noble duty if, guided by the fall of spirometrical readings in an individual case, we shall have advised our patient, who may yet appear to enjoy good health, to be aware of the discrepancy of vital capacity, to try by all means of diet, gymnastics, hygienic habits, climate, proper occupation, &c., not only to maintain his *status quo* of health, but to improve it by all means, and to endeavour to attain or exceed his general standard of breathing volume if possible.

Under no circumstances have we a right to declare a man healthy as long as his vital capacity remains below the average, however unable we may be to see or make out the cause of this deficiency. If, on the other hand, we have done our best to satisfy our own conscience, we may also feel sure that some good may result to our patient, who puts all his trust in our ability and good will. But the spirometer will help us considerably in many instances if skilfully used, and

it is not to be looked upon so lightly or superficially as some authors in their books on consumption and diseases of the chest do. Why? evidently because the spirometer is not able to give them a direct and palpable diagnosis without any further mental exertion and trouble; because it will tell them nothing of the distribution of air in the lungs, nor will it point out the side and region receiving too much or too little air; for these reasons they say the spirometer is of no use. But then Dr. Jagielski continues, if you cannot ask all that of the spirometer to call it useful, let us utilise at least that little we can obtain from its readings. If, however, we shall get into the habit of using the spirometer as much as the balance to ascertain the weight of a person then we shall be able to conclude quite as much and more from the knowledge of deficient individual vital capacity. It will teach us the state of general health of an individual, and tell us when we have to exclude a man from a certain work or occupation. In the instance of recruits, it is generally admitted that the spirometer will ascertain roughly and rapidly the pulmonary soundness of a body of men, and therefore the results are accepted as significant.

The Medical Press and Circular.

ARMY MEDICAL REFORM.

We understand that, in reply to a circular issued on the subject of the grievances of army medical officers, a committee of the Council of the College of Surgeons in Ireland appointed to inquire into the matter, have received many valuable suggestions for the improvement of the department from several of their Fellows and Licentiates in the service. We believe the military surgeons consulted were unanimous in recommending the following, viz.:—

The compulsory retirement of administrative officers at sixty years of age, executive officers at fifty-five, as heretofore. Promotion after a fixed number of years, twelve in the opinion of the majority. Forage, a stable and a groom to be an appanage of rank, the latter to carry with it all the privileges and allowances of the corresponding military grades. A voluntary retirement of 18s. 6d. after twenty years' service, to be increased to £1 per diem if invalidated by a medical board.

No ambiguity in the wording of any warrant affecting the officers of the department.

Stores to be in charge of a purveying staff. Individual regimental medical officers to be compensated for any losses they may have sustained. The question of the organisation of the department was not touched upon.

In our last number we commented upon the very great unpopularity of the service as a life career for a young surgeon. We trust that the Council of the College may do something in the way of improvement, by adopting in their entirety the foregoing propositions, which appear sensible, and to the point. In the late Naval Medical Warrant the regulation was laid down that no administrative officer should serve after he had reached [sixty years—a regulation of great importance, the advantage of which we hope will be strongly urged.

Without compulsory retirements at the top of the ladder the juniors can never hope for advancement in position and emoluments, and we fully concur with the late remarks of a medical contemporary upon this subject. It seems to us that all reasonable demands would be gained in the way of promotion if the latter was guaranteed after fifteen years service, or rather that no medical officer should be required to serve longer in the junior grade, for as the present

numbers in the senior ranks decrease, promotion will probably regain its normal flow. There can be no question that forage for a horse, a stable, and a groom should be allowed to every military surgeon ranking as a field officer. This privilege of drawing forage was guaranteed by Clause 17 of the Royal Warrant of 1858, as were the other advantages of the corresponding military grades. As long as we can remember, an adequate retirement after *twenty years' service* has been demanded by our military *confrères*, and the terms proposed, which we believe are identical with those of the Parliamentary Bills Committee of the British Medical Association, do not seem very outrageous. Surely after twenty years' service in every clime a man should look confidently forward to his pound a day if in broken health and unfit to serve? Upon the future organisation of the department we do not venture to offer an opinion, excepting this, that in our view it should be either one thing or the other. Our contemporary the *Globe*, of the 18th inst., gives circulation to a rumour that a "royal medical staff corps" is to be formed, the officers of which should be "executive" as far as the command of the army hospital corps is concerned, and that to this staff corps should be given sole charge and control in the military hospitals, subject only to the authority of the general officer commanding, and that medical officers should be relieved of all charge of stores and medical comforts, and that all medical officers should be placed upon a foreign service roster, and that they should proceed abroad as their turn arrived, irrespective of any appointment they might be holding at the time. Such a system impartially administered would, at all events, be an improvement upon the present arrangement, which appears to be neither staff nor regimental. A great deal has been written upon the grievances of the department, but nothing appears to us so great a grievance as that some officers should contrive to pass the greater portion of an official lifetime at home, while their less fortunate brethren on the staff have in consequence been obliged to serve far longer in all sorts of abominable climates. In the Guards, medical officers who do not take their turn of foreign service are, we believe, precluded from promotion to the rank of administrative officers, and we think very justly, as they could have no practical experience of tropical disease. A somewhat similar rule might be introduced with advantage into the general service. We should say ten years' foreign service should be a *sine qua non* for promotion.

THE FRAUDULENT TRADERS PROTECTION BILL.

THE Council of the Pharmaceutical Society, which occupies, in the matter of adulteration, an awkwardly intermediate position between the shop-keeping interests of chemists and the desire to maintain the reputation of pharmacy untainted by the imputation of trade dodgery, has had a serious debate upon the Adulteration Bill of Mr. Sclater-Booth, from which we take a few extracts.

One member considered "that the law ought to punish those who were really the guilty persons; whereas a man who bought an inferior article and sold it in the same state, if a small amount of impurity were found in it,

might be fined or punished. The present amended Bill, he believed, was one which would not pass in its present form, and in fact there were many clauses in it which opened the door to extensive adulteration and to undoing the good work which the present Act had done."

Mr. Frazer said that "the present Bill as it now stood was very imperfect; the Select Committee, he believed, having been overweighed by manufacturers, and the Bill, therefore, tended to protect the fraudulent dealer, and not the public, in whose interest it professed to be framed. His own view was rather in accordance with that put forward in the MEDICAL PRESS AND CIRCULAR to the effect that the only honest method of dealing with these matters would be to allow traders to sell anything they liked so long as it was not injurious to life, but to force them to state honestly the true constituents of what they sold. Rather than pass the present Bill he should prefer to abolish the old Act and fall back on the common law, which punished imposition or misrepresentation; whereas, if the present Bill became law, he might sell scammony containing three-fourths of flour with impunity, simply because it did not contain anything injurious to health. If any resolution were passed, he should prefer one, though he did not suppose it would find a seconder, to the effect that the present Act had tended greatly to the protection of the public, and that the present Bill would lessen that protection. Any hardships which had arisen under the present Act he believed to have arisen more from its administration than its principle."

The speech of the occasion was, however, that of Mr. Schacht, who distinguished himself by an enunciation of opinion which we should have considered to be ironical if we did not observe that it was taken quite *à sérieux* by subsequent speakers.

"His own opinion," Mr. Schacht said, "was that the buying public ought to be fined. Here was an opinion put forward that the responsibility ought to be taken from the retailer and put on the wholesale dealer, and from him to the importer, and possibly from him again to the manufacturer. But suppose you got to the manufacturer, what would be his defence? He would say that he would much rather manufacture a perfectly pure article, but he was required by his customers to produce something imperfect at a lower price. The wholesale dealer would say the same thing, and so it would go on; the retailer also would say that he would much rather sell a perfectly pure article, but his customers insisted on having two-pennyworth of stuff for a penny, and thus he was obliged to supply them with an inferior article. That was the whole story. It was really the public who were to blame, and he thought they ought to pay the penalty of their misdeeds by being poisoned."

A deputation was appointed to wait upon the Government, and of the proceedings of this deputation a brief account is given in the society's journal.

It was pointed out, we are told, that the proposed amendments appearing on the notice paper of the House of Commons included one to erase the word "knowingly" in almost every case in which it occurs in the Bill. The injustice of doing this, so far as regards the retailer, was urgently represented, and great stress was laid on maintaining the principle expressed by that word in the Bill.

The word should be properly interpreted *fraudulently*, and it should certainly be open to an accused party to prove that he had not been guilty of fraud. He might do this in various ways, one being a *proof* that he bought his drugs in the best market, at a fair price, and with a reasonable belief in their purity; and *proving* this he should be regarded as an innocent man.

Both the speakers and the Editor seem to have forgotten altogether the fact that the retailer's responsibility for the good quality of his goods, which they think it monstrous to impose upon druggists and grocers, is placed by the law and by custom upon every other trader. To require that articles of food and drugs shall be what they profess to be demands on the part of the vendor no analytical skill whatever. It would indeed be ridiculous, unjust, and impracticable to oblige the seller of a tin of mustard to answer for its purity of *his own knowledge*; but it is fair and simple to compel him to obtain a warrant of that purity from the manufacturer. The retailer has only to state explicitly to the manufacturer what it is that he wants. If he receives an inferior article, sells it, and is prosecuted, he has a safe and immediate remedy against the manufacturer who cheated him, and that trader will take good care that he supplies nothing but what is unmistakably demanded of him.

Notes on Current Topics.

Veiled Obscenity.

THE *Irish Builder*, referring to our recent article on this subject, says:—

"THE MEDICAL PRESS, in an article under the title of 'Veiled Obscenity,' shows up the rascality of obscene quacks. It says that a Dublin daily in which the advertisement was found 'was entirely unconscious (?) of its character, and at once stopped it.' We regret to say that other Dublin weeklies and dailies continue the advertisement alluded to, and others of quite as bad a character. On several occasions we have made war upon these scoundrelly class of medical quacks, and unearthed them in their dens in London and Dublin, giving their real names and addresses, for which we were threatened with actions at law. We hold that the proprietors, or editors of the papers which publish this class of advertisements are nearly as bad as the quacks themselves. We assert, and can prove, moreover, that the said proprietors, editors, and newspaper managers are quite conscious of the infamy and iniquity they are aiding and abetting by the publicity they afford these consummate scoundrels, some of whom are convicted swindlers."

The latter phrase of our contemporary's justly indignant remarks involves a very serious charge against the Dublin press. We are of an unhesitating opinion that the editor or proprietor of any newspaper who admits to its columns the advertisement to which we referred, being aware of its character and objects, is guilty of selling the morality of his journal, and insulting the decency of his readers for the sake of the miserable gain obtained from the trade in such advertisements. He is a wilful participant in an infamous plot against the morals of the public, and to our mind—almost as worthy of the intervention of Lord Campbell's Act as the obscene print-sellers of

Holywell Street. We shall certainly not flinch from publishing the name of any journal in which we find this disgraceful announcement, if we find that the advertisement has been continued after the editor has had knowledge of its nature.

Suspended Animation in New-born Children.

DR. C. R. BUCKINGHAM (*Boston Medical and Surgical Journal*, No. 7, 1875), advises in such cases to take the child up in a dry towel, hold it with the scapulae on the palm of left hand, the finger and thumb embracing the occiput, the finger and thumb of right hand should close its nostrils. Apply the mouth to the child's mouth, and try to inflate its lungs, and press the head forcibly backwards, to close the passage to the oesophagus. Inflate from 10 to 15 times a minute.

Ophthalmia Neonatorum.

DR. DENBY (*Boston Medical and Surgical Journal*, No. 7, 1875) says that Dr. Williams, of Boston, stands almost alone in condemning the use of nitrate of silver lotions in this complaint. As soon as the purulent secretion commences, the upper and lower lids should be everted, and being freed from secretion, a large camel-hair brush, dipped in a solution of nitrate of silver, of ten grains to the ounce, is passed over them, then dipped in cold water and several times applied. The pain, at first acute, soon subsides. Only in exceptional cases will this be required again towards evening. If this be not sufficient, the stick of nitrate of silver of Graefe, the *lapis mitigatus*, formed with twice the bulk of nitre to one of nitrate of silver, may be applied. These are not dangerous remedies, says Dr. Denby, and they supersede all other treatment, except strict attention to cleanliness.

Fungous Disease of the Ear.

DR. J. P. CASSELLS, of Glasgow, contributes to the January number of the *Glasgow Medical Journal* an interesting and instructive paper on "Fungus Ear Disease" (*Otitis parasitica*), a form of disease which he believes has been almost overlooked in England. He, it appears, came to this conclusion from the fact that, in 1874, Hinton "had not seen such a form of ear disease, nor did he know of an aural surgeon who had." From this circumstance Dr. Cassells formed the determination to investigate every case of ear disease with more care the symptoms of which gave reasonable grounds for suspecting the presence of aural fungus. The result was that in May, 1874, he discovered three cases, and in June, a case in which fungus (*Aspergillus nigricans*) was found in both ears, since which he has seen several cases in private practice. He goes on to say that no English observer had hitherto recorded such a case, and therefore the discovery was considered sufficiently important to merit publication. In this, however, he is mistaken, for in April, 1857, a member of the profession, Mr. John Grove, published a case in the *Quarterly Journal of Microscopical Science* (1857), and gave some admirable drawings of the fungus fruit and its floccular mycelium, magnified 400 diameters, and which were found to ramify beneath the

surface and amongst the hexagonal pavement epithelium. This gentleman tells us also that in the previous September of 1856 he met with a beautiful specimen of fungoid growth removed from the ear of a gentleman who had suffered much from what was thought to be inflammation of the external meatus auditorius. At the end of some days' treatment it was noticed that a peculiar flocculent mass came away after syringing the ear, and which upon examination proved to be a fungus. The disease was speedily cured by the daily use of an alum injection.

Mr. Grove adds that "the only instance of a growth of the kind in a like structure, is given in Robin's work," and he quotes from a paper by Mayer, in "Muller's Archives," who speaks of a fungoid growth found in some cysts removed from the ear of a child, eight years old, who suffered from a scrofulous discharge from the external meatus. He then proceeds to give certain marked differences in the fungus, its mycelium, character of its spores, and shows in what respects his own case differs from that described by Robin, and it is tolerably certain, both from his drawings and description, that Mr. Grove published in 1857 a previously unobserved fungoid growth occurring in the human ear. Nevertheless, Dr. Cassell's paper, read before the Medico-Chirurgical Society in November, 1874, and lately reproduced in the *Glasgow Medical Journal*, is one of considerable interest, and will serve to direct the particular attention of aural practitioners to "otitis parasitica."

The Nobility of Labour again.

A CURIOUS bit of evidence respecting the condition of the mining population in the north is given by the *Durham Advertiser*. The other day an eminent dentist in that city received the following note from a pitman :—

"Lanchester, Fuby 6th. Ser, I nockt 5 teeth down my wifes throate on Saturday, and I wunt them put in again. Will you tell me wat it will cos, and she will come and see you nex weak."

The question of terms having been satisfactorily settled, this business-like order was duly executed and paid for.

A Toothsome Beverage.

It appears from the recently issued report of the Inland Revenue Commissioners that one person has been detected and convicted of selling methylated spirit as a beverage. The spirit had not been purified, but only sweetened, coloured, and reduced in strength. The Commissioners state that it is difficult to understand how the taste of persons could become so depraved; the spirits were consumed by persons who were in very humble circumstances.

The Metropolitan Hospital Sunday Fund.

A MEETING, under the presidency of the Lord Mayor, was convened for Tuesday last, to consider the resolutions passed at the meeting of the 8th inst. Several letters were read from members of the Council, among them one from Sir James Paget, declining to serve on the Council if these resolutions were carried into effect. The Rev. Canon Miller and other ministers protested against the proceedings at the last meeting, at the same time observing

that as the money must be collected before it could be distributed, it would have been better to have consulted those who were to preach for the Fund rather than those who in all probability would never take any further interest in the matter.

Sir Rutherford Alcock moved, and the Rev. T. J. Rowsell seconded, the following proposition :—"That the Council declines to act upon the resolutions passed at the public meeting on the 8th inst., believing that those relating to the constitution of the Distribution Committee, and restricting its discretionary power, would, if carried into effect, prove adverse to the just and generally satisfactory administration of the Fund."

An amendment to this was proposed by Mr. Brudenell Carter, seconded by the Bishop of London :—"That this Council, having been appointed by the annual public meeting held on the 4th of January, to make arrangements for the collection and distribution of the Metropolitan Hospital Sunday Fund for the current year, declines to hold itself bound by, or to accept otherwise than as recommendations worthy of being considered, the resolutions of any meeting held during its tenure of office."

This resolution was carried, together with another proposed by the Rev. Dr. Kennedy, to the effect that, before any further action be taken, the ministers of religion throughout the metropolis, with one member of each congregation, be invited to a conference at the Mansion House on the subject.

Societe Belge de Microscopie.

A YEAR or two ago it was announced that the Brussels savants were intent upon establishing a microscopical society upon the model of the English societies. The attempt, we are now told, has been attended with great success, a large number of Belgian scientific and medical men having already joined it, and its influence will no doubt be proportionally great upon the future of microscopical research. The Society, at its last meeting, unanimously conferred upon Mr. Jabez Hogg "the highest title it has to bestow—viz., that of Membre Honoraire, in consideration of his valuable contributions to microscopical science."

Unsatisfactory State of the Public Health of Ireland.

THE Registrar-General reports that the death-rate of Ireland for the quarter ending last December was considerably over the average of the same quarter of the previous five years, partly owing to the increased fatality from scarlet-fever, and partly to the large mortality amongst old people caused by the variable weather during the quarter. The deaths from scarlet-fever in the province of Ulster last quarter were more than double the number in the September quarter; in Connaught, also, the disease spread considerably; whilst in Leinster and Munster it remained stationary.

The health of Ireland during the last quarter of last year was far from satisfactory. The number of deaths registered were 1,147 more than those registered in the same quarter of the previous year, and as many as 3,069 more than those which occurred in the same quarter of 1874. Scarlet-fever destroyed not less than 1,427; the worst

"not less" are used by the Registrar-General advisedly, for there can be little doubt that very many deaths resulting from scarlet-fever have been returned under the head of dropsy.

The wave of scarlet-fever broke with unequal force over the four provinces. Ulster suffered most, having lost 812 persons; next in order came Leinster, where 442 deaths occurred; then in Connaught there were 104 deaths; and the remaining 69 deaths took place in Munster. During the first quarter of the last year scarlet-fever killed 760 persons; in the second quarter 731; in the third quarter 978; and, as before stated, in the fourth quarter 1,427, thus making a total of 3,894 victims to the plague.

The report of the Registrar of Kilrea district, Ballymoney Union, affords further proof, if such were needed, of the very contagious nature of the disease, and of the extreme tenacity with which the *materies morbi* clings to a habitation where scarlatina has existed. He says: "The contagion was brought from Coleraine into the family of a labourer of this town, with whose three young children it rapidly assumed a malignant form and ended fatally. When the first case appeared the other children were removed from the house, but on their return, within a month, they soon caught the disease, though the premises had been limewashed and thoroughly ventilated. About the same time it attacked the eight children of a farmer living in a hilly part of the district, and two of them succumbed. In these latter cases the contagion was also traceable to another district."

At Rathcoole, Celbridge, the Registrar reports that an outbreak of the disease in his district was due to its importation from a distant wake.

Diphtheria, which, as is known, is usually concurrent with scarlatina, caused 173 deaths—84 in Ulster, 56 in Leinster, 28 in Munster, and 5 in Connaught. In Coleraine Union there were 10 deaths from it, of which 8 (out of a total mortality of 29) occurred in Articlave district.

Whooping-cough proved fatal in 376 cases, against 592 in the same quarter of the previous year, a decrease which is ascribable to the great mortality of children from scarlatina.

Fever caused 634 deaths, against 640 in the same quarter of 1873, and 705 in the third quarter of 1874.

Small-pox numbered 148 deaths, against 128 in preceding quarter, and 79 in the last quarter of 1873. Of these deaths, 108 occurred in Connaught, 39 in Ulster, 1 in Munster, and none in Leinster. In the Swinford Union 53 deaths took place from the disease alone, and the Registrar of Kiltimagh district in that union reports that the disease "is still making its ravages in the district, owing, in great measure, to inoculation." Of 49 deaths in Balla district, Castlebar, no less than 23 resulted from small-pox, and the Registrar reports that inoculation was carried on to "a fearful extent." This is the union where the guardians the other day decided to postpone any vaccination or inoculation prosecutions for another month.

Birmingham Medical Institute.

MANY of the medical men at Birmingham, and nearly all the local papers, seem on the side of admitting professed homœopaths to membership of the Birmingham

Medical Institute. Mr. Pemberton has sent round to fourteen medical men a circular to be signed, to the effect that the signer of it is of opinion that all those practising as professed homœopaths, however legally qualified, should not be elected members so long as they assume a mode of practice and maintain a name calculated to mark them from the general body of practitioners.

John Hunter on Ovariectomy.

JOHN HUNTER is reported to have said: "I cannot see any reason why, when the disease can be ascertained in an early stage, we should not make an opening into the abdomen and extract the cyst. Why should not a woman suffer spaying as well as other animals do? The merely making an opening into the abdomen would never be followed by death in consequence of it."

Excessive and Long-maintained High Temperature after Injury to the Spine—Recovery.

MR. J. W. TEALE has brought before the Clinical Society a case in which a temperature ranging from 108 to 122 deg. and upwards had been maintained for a period of nearly nine weeks. The case had also been seen by Mr. Pridgin Teale. The patient, Miss G., was thrown from her horse on September 5th, 1874, as the animal was trying to take a five-barred gate at a standing jump. The horse fell upon the lady, and rolled two or three times backwards and forwards over her chest, as she lay on the ground, which was covered with large rough stones. Temporary unconsciousness followed. The fifth and sixth left ribs were found to have sustained a simple fracture in the middle of their length; she was conscious, but collapsed, complained of great pain in the back, and was severely bruised at various parts of the body. For several days after the accident, there was some feverishness; the temperature reached 101 deg., but became normal in a fortnight. The ribs united readily, and the patient was apparently convalescing, though she had pain and tenderness over the spine, especially about the sixth dorsal vertebra. It was considered that the pain and the slight feverishness were due to subacute inflammation of the spinal ligaments, and perfect rest on a water-bed was advised. During October the temperature remained at 100 or 101 deg.; there was pain, with tenderness, over the spine; sleep was disturbed; occasional twitchings of the legs occurred; and there was a feeling as of a cord tied tightly round the waist. The arms were unaffected. Leeches and ice-bags to the spine were employed; but the temperature slowly rose until, on November 3rd, it was 103.5 deg.; on November 6th, 106 deg.; and on the 7th, 107 deg. The respirations were unaffected; the pulse did not exceed 100. On November 7th it was thought that she had inflammation of the spinal ligaments and intervertebral substances, and possibly of the membranes of the cord, but that the cord itself was not primarily affected, except by pressure of neighbouring inflamed parts, as there was no paralysis of sensation or motion about the legs or sphincters, and it was determined to bring the system gently under the influence of mercury, by means of ointment applied to the thighs. On November 8th the

temperature was 110 deg. ; on the 11th, 12th, and 13th it was 111, 113, and 114 deg. ; whilst on the 14th the index of the thermometer was buried in the bulb at the top of the instrument at a point above 122 deg. The pulse rose to 120, and became small, thready, and at times scarcely perceptible. Rapid emaciation occurred ; there was intense pain along the spine, which was relieved by frequent hypodermic injections of morphia, and death from exhaustion seemed imminent. At times the power of swallowing was lost, once for forty-eight hours ; nutrient enemata were given, and ice-bags applied to the spine. On November 16th the mercurial ointment was discontinued, the gums being slightly tender ; and there was from that date an improvement in the general symptoms, though the temperature remained still as high as ever. The power of swallowing returned ; the pulse fell to 110, and improved in quality ; the spinal pain diminished ; the twitchings in the legs were less frequent, and the patient could raise the legs more freely. The extraordinarily high readings of the thermometer ceased now to cause alarm, the patient having lived so many weeks with a temperature hitherto supposed to be incompatible with life. On December 12th the tongue became suddenly swollen, causing great distress, which subsided in about twenty-four hours. Thenceforward more decided improvement set in. The appetite increased ; flesh and power were regained more rapidly, though the temperature still ranged from 110 to 114 deg. On January 7th, 1875, the temperature fell to 104 deg. ; on the 8th to 102 deg. ; and on the 10th it was normal. On the 12th the patient could take a few steps about the room, a slight drag of the left leg being perceptible. On the 22nd she walked one hundred yards in the open air. Mr. Teale thought that the result proved that the cord itself had not been seriously implicated, and that an excessive and long-maintained high temperature was not necessarily destructive of life. He said that seven thermometers had at different times been used to register these high temperatures, four of which had been since verified at Kew. Only one thermometer could be found which registered a temperature above 118 deg. ; that one was marked up to 122 deg., and with that instrument the highest readings were taken. On December 1st, for the fifth time the index was buried in the bulb ; as it was then found it still remained, and had been brought to the meeting for inspection. It was marked to 122 deg. The temperature was often taken in both axillæ at the same time, the instruments being reversed at each visit. The temperature between the thighs was generally found nearly to correspond with that registered in the armpits. Once, on December 10th, the temperature in the rectum was taken, and was found to be 111 deg., that in the axillæ at the same time being 110.4 deg. The patient could never bear the thermometer to be placed beneath the tongue. The thermometers were inspected by two or three trustworthy witnesses before and after each application, and the results were always immediately recorded in writing. No hot-water bottles were near the axillæ, as had been good-naturedly suggested. Sometimes when the thermometrical readings were highest, the hands, feet, and forehead were icy cold. The urine, during the period of high temperature, was very scanty, and a mass of lithates ; it was passed with difficulty into hot towels, so that neither

the amount of urea it contained, nor the specific gravity, could be estimated. It was found to be free from albumen on three or four different occasions. The bowels were relieved every third day by enemata ; the menses recurred once after the accident at the proper date, and were then suppressed until January 26th, when they commenced and pursued a normal course. A large chart of the thermometric readings was exhibited to the members of the Society, and showed the rapid alteration of temperature which had occurred, without apparent alteration in the condition of the patient ; thus, on November 12th, at 10.10 p.m., the temperature was 113.6 deg. ; on the 13th, at 4 a.m., it was 122 deg. ; on the 13th, at 10 a.m., it was 114.3 deg. During seven weeks the temperature never fell below 108 deg., and rarely below 110 deg. Whether the high temperature was due to lesion of the ganglia of the sympathetic, Mr. Teale could not venture to surmise. There was never at any time distinct loss of sensation. The temperature was usually higher in the left than the right axilla ; the left leg was now slightly the weaker ; and it was the left ribs which were broken. Mr. J. W. Teale regretted that, since his paper had been forwarded to the Secretary, his patient had had a relapse, from which she was still in some degree suffering. After Miss G. had been convalescent for five weeks, he had reluctantly consented to her return home, and the effect of the railway journey, of 100 miles, had been in some measure to bring back the pain in the back, and a return of the high temperature, which had ranged from 105 degs. to 110 degs., and which was now again slowly falling. There had been no relapse of the more serious symptoms. Mr. Callender said that in no case of injury to the spine with recovery had he known the temperature to be above 107 degs. Dr. Greenhow had had cases of hyperpyrexia in rheumatic and typhoid fevers often under his care, but had never witnessed a rise so high as this. He had seen a patient with a temperature of 110 degs., but never one to recover. Dr. Farquharson contrasted this with a case observed by Van der Kolk, in which, with dislocation of the first dorsal vertebra and injury of the spinal cord, the temperature fell to 82. Some observers held that, if the cord was injured near the brain, the temperature was high ; others asserted the contrary. Dr. Murchison had laid it down that in fever a temperature of 107 degs. was incompatible with life, even for a day. At post-mortem examinations in such cases, fatty degeneration of the brain and heart was found to have occurred. Mr. Hutchinson expected that the maximum temperature laid down by authorities as compatible with life in fevers would not apply to cases of injury to the spine. After injury to the spine low in the neck, there might be very high or very low temperature without apparently any reason. He mentioned the case of a man who had received an injury to his cervical spine, producing paraplegia, and had a temperature which never rose above 4 degs. below the normal. He was quite cold, even to the penis, which was turgid with blood, so that there was continual priapism ; his face was quite cold, although he looked to be very well. He died on the fifth day. In such cases, however, there was mostly an exaltation of temperature, often to 110 degs. within twenty-four hours after the accident. He thought the mischief in Mr.

Teale's case was in the spinal cord, although it was not a seriously disorganising disease. Mr. Pridgin Teale wished to add his testimony to the accuracy with which the case had been recorded. He himself took the temperature when it was at 110 degs., and three weeks subsequently at 114 degs. It was clear that we must give up the idea that temperature *per se* was an element of high danger. No injuries apparently were capable of raising the temperature so quickly to a high degree as those of the nervous centres. A gentleman, who at 5 a.m. received a compound fracture of his skull with crush of brain, was found at 5 p.m. to have a temperature of 109 degs., and was then dying. With apoplexy the temperature of the body often rose enormously. He hoped the time might shortly come when physiology might be able to throw some further light on these various points. In reply, Mr. J. W. Teale said that the pulse of his patient never exceeded 120, and was usually between 90 and 100. The respirations were never anything but normal, though sometimes excessively feeble.

The Sanitary Necessities of Ireland.

We are glad to observe from the quarterly reports of sanitary medical officers throughout Ireland that the Public Health Act has already in many districts produced good results, for which desirable consummation we have to thank the courage and energy of the medical officers themselves, and certainly not the large-mindedness, ardour, or generosity of the guardians. We need hardly say that, speaking generally, where an effort for the sanitary improvement of a district has been made, it has been made, at least, with the toleration of the guardians, and frequently against their passive opposition. For the information of our legislators, who, we believe, will be pestered with petitions against the operation of the Irish Public Health Act, we quote one or two of the reports of the sanitary medical officers as an illustration of the condition of things which Irish guardians think is quite well enough.

The Registrar of Cootehill district reports the prevalence of scarlatina in his district, and says:—

"On the 24th December I was called on to see a family, six in number; four were ill with scarlatina, crowded in a small room; in an adjoining room six cows were kept at night; the manure was a foot deep in the apartment occupied by the cattle (which is the better room of the two). I have reported the case to the relieving officer and the sanitary authorities. I have since heard one of the number is dead from ascites, consequent on scarlatina and the filth of the place."

The Ardmore (Youghal) Registrar says:—

"The sanitary state of this district is disgraceful. The principal well in the village, while in its present condition, is nothing more than a shallow hole in the ground, into which all kinds of filth and dirt drain."

And the medical officer at Bruff (Kilmallock) reports:—

"The residences of the labouring classes are, for the most part, small, wretched hovels, without any accommodation whatever; in some there are neither back-doors nor chimneys, and the windows are so small as to be of no practical value for ventilation. Where this state of things prevails, as it actually does in the narrow lanes of this town and also in the country districts, the consequences are—within, overcrowding, increased invariably by the presence of a pig-sty, and occasionally by a horse or an ass; and without, the collecting of dung, house-soil, and filth into heaps or pits close to the doors. I am at present attend-

ing a poor man for inflammation of the lungs in one of those miserable abodes in which are crowded together six in family, a horse, and a pig, *all in one room*, capable of containing not more than about 700 cubic feet of air. Until something is done to improve the dwellings of the labouring classes and to construct them on better hygienic principles, the progress of sanitary matters in this country will be slow indeed."

DR. ALFRED MEADOWS, Vice-president of the Obstetrical Society of London, has been elected a Corresponding member of the Medical Society of St. Petersburg.

At the annual general meeting of the Royal Irish Academy for the election of a president and council for the ensuing year, Dr. Stokes, F.R.S., was re-elected to the office of president.

THERE was a very large attendance at the Albert Hall on Saturday evening, when the Amateur Orchestral Society gave a concert in aid of the Middlesex Hospital funds.

THE inter-Universities annual struggle on the Thames on Saturday ended in a very hollow victory for Oxford. The want of *physique* was painfully apparent at the close of the race in some of the Cambridge men.

A NEW medical journal made its appearance last Monday, entitled *The Medical Enquirer*. Its mission appears to be representative of the objectors to the Contagious Diseases Acts, and the repeal of these measures.

A MEETING will be held at Willis's Rooms to-morrow, the 25th March, at 4 o'clock, to consider the subject of a Memorial to the late Sir Ranald Martin, when his friends and admirers are invited to attend. Sir T. Galbraith Lcgan, K.C.B., has kindly consented to preside.

THE appointment of a surgeon to the County Dublin Prison, at Kilmainham, vacant by the death of the late Dr. Thornhill, took place on Friday last, the choice being vested in the Board of Superintendence, and the salary of the office £150. The candidates were multitudinous, and Dr. Rutherford Kirkpatrick was chosen.
